We have investigated the role of CseA in the $\sigma^E$ cell envelope stress response of the gram-positive bacterium *Streptomyces coelicolor*. $\sigma^E$ is an extracytoplasmic function RNA polymerase sigma factor required for normal cell envelope integrity in *S. coelicolor*. $\sigma^E$ is encoded within a four-gene operon that also encodes CseA, a protein of unknown function, CseB, a response regulator and CseC, a transmembrane sensor histidine kinase (Cse represents control of sigma $E$). Previous work has shown that transcription of the *sigE* gene is completely dependent on the CseBC two-component system and that the CseBC- $\sigma^E$ signal transduction system is induced by a wide variety of cell-wall-damaging agents. Here we address the role of CseA, a protein with no homologues outside the streptomycetes. We show that CseA is a novel lipoprotein localized to the extracytoplasmic face of the cell membrane and that loss of CseA results in upregulation of the *sigE* promoter.
