INVESTIGATING PHYSICAL AND COGNITIVE CHANGES OVER TWO YEARS IN PATIENTS WITH MODERATE TO LATE STAGE PARKINSON'S

DISEASE IN NORTHUMBRIA

$L.\ MCDONALD^{A},\ I.\ SAYERS^{A},\ S.\ DEMPSEY^{A},\ W.\ GRAY^{B},\ S.\ DODDS^{B},\ A.\ HAND^{B,C}\ AND\ R.\ WALKER^{A,B}$

- A. Newcastle University
- B. Northumbria Healthcare NHS Foundation Trust
 - Northumbria University

Background

- Parkinson's disease (PD) patients face both motor and non-motor symptoms, with nonmotor shown to have a greater impact on quality of life¹.
- Studies suggest that the Montreal Cognitive
 Assessment (MoCA) is more sensitive than the
 Mini Mental State Exam (MMSE) for detecting
 cognitive decline in PD².
- Grip strength has been shown to be a better predictor of decline in function compared to gait and balance³.

Methods

- The Northumbria Care Needs Project is investigating the care requirements of Hoehn and Yahr score III-V PD patients. Only patients with complete baseline and follow-up data were included.
- Follow up data were collected between 23/11/16 and 29/01/19, two years after patients were seen at baseline.
- We assessed changes in timed up and go (TUG), grip strength, MoCA and MMSE scores, and explored which areas of cognition were most commonly affected. TUG was defined as normal (≤10s), good (≤20s) or problematic (>20s).
- Decline in grip strength was compared against patient's MDS-UPDRS scores for hand movements (question 3.5).

Results

Physical changes:

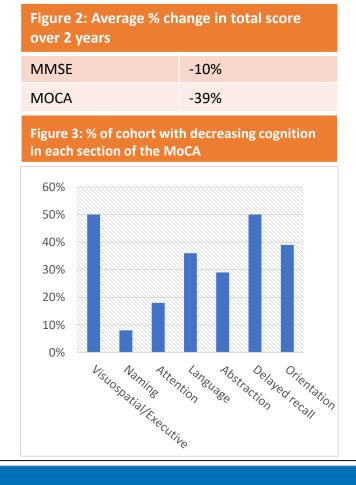

- <u>TUG</u> 75/162 patients were analysed:
- 33% had a decrease
- 15% had an increase
- Of the patients with no change, around half had a "problematic" TUG at baseline.
- <u>Grip strength</u> 56/162 patients were analysed:
- There was an overall decline in grip strength
- Very few showed a reduction in hand movement (11% right hand, 7% left hand). Surprisingly the majority improved (47% right, 65% left).

Figure 1: Change in TUG over two years Increase in TUG Number of sample Increase in TUG Decrease in TUG Change A: 17 B: 21

A: "Problematic" at baseline
B: Not "Problematic" at baseline

Cognitive changes:

64/162 patients completed cognitive assessment.

Conclusion/Discussion

- Cognitive decline is more apparent on testing with the MoCA than the MMSE. Visuospatial/executive function and delayed recall are most, and naming difficulty least, commonly affected.
- The majority of patients TUG rating stayed static although this may have been due to many having already progressed to "Problematic".
- Improvements in TUG and grip strength may be due to input from physiotherapy and medication changes.
- There was no link between decline in grip strength and assessment of hand movements by MDS-UPDRS scale.
