Abstract: Pd-based metallenes have attracted great attention recently as newly burgeoning two-dimensional (2D) materials, attributed to their significantly increased active surface areas and intrinsic electrocatalytic activities. Therefore, they could be used as a potential candidate as the high performance electrocatalyst for methanol oxidation reactions (MOR) in the direct methanol fuel cell. Herein, a new strategy is proposed to fabricate NiCoPd inlaid NiCo-bimetallene (NiCoPd/NiCo-bimetallene) by structure directing effect of 18-crown-6 ether under ultrasonic-pulse interface together with HCHO reduction and atom-diffusion-aging process. NiCoPd ternary-alloy with uniformly dispersed Pd active sites are decorated onto NiCo-bimetallenes, achieving remarkably enhancing the effective utilization of Pd atoms. What's more, the intrinsic activity is enhanced by the 'bifunctional mechanism' of NiCo-bimetallene adsorption of intermediate species and increased Pd active sites. Moreover, the anti-CO poisoning ability is optimized through 'alloying ligand effect' of NiCoPd. Therefore, the NiCoPd/NiCo-bimetallene exhibits excellent mass activity for MOR, which is higher than commercial Pd/C. This work suggests the new way of Pd-based metallenes catalyst approach to efficiently electrocatalytic MOR.

1. Introduction

Since the discovery of graphene in 2004,[1,2] it has been a hot research topic to search for graphene derived and other new types of two-dimensional (2D) materials (or called Xenes).[3,4] Among them, metallenes have recently attracted great attention in the field of direct methanol fuel cell (DMFC) as one of newly burgeoning 2D materials.[5] DMFC has the characteristics of high energy transition efficiency, convenient handling process, and environmental friendliness,[6] is considered as one of key advanced energy conversion and storage technologies to solve the rising energy demand.[7] Its performance is largely determined by the performance of anodic methanol oxidation reactions (MOR). Notably, Pd-based metallene catalysts have been proved as one of the best electrocatalysts for MOR, due to their excellent mass activity, such as Pd_3Pb metallene,[8] Pt-on-Pd dendritic metallene,[9] and porous Pd metallene.[10] However, the high cost and poor durability of these Pd-based metallene catalysts are the key obstacle for their commercial applications. In this regard, alloying Pd with other cheap transition metals can significantly reduce the cost. More importantly, Pd-based alloy catalyst, such as PdNi,[11] FePtPd,[12] CoPtPd,[13] CuFePd,[14] have further enhanced the anti-CO poisoning ability toward MOR, which is attributed to the following facts. The adsorption of hydroxyl intermediate (OH_{ads}) on transition metal groups (Ni, Bi, Ni, Cu, Co, and Sn) in Pd-based alloy can not only promote the oxidation of CO and $-\!\!-CH_x$ species,[15-17] also release more active sites of Pd for electrocatalysis and provide oxygen sources for CO-like poisoning species, which are adsorbed on Pd to be transformed into CO_2.[18] What's more, the transition metals in the Pd-based alloy can regulate electron structures of Pd and reduce the adsorption energy between the toxic species and Pd surface.[19-22] However, from the perspective of structure, the smaller specific surface area of Pd-based alloy catalyst reported above will lead to lower utilization of active sites,[11-14] while the advantages of metallene structure in the following aspects are more obvious. The atomically thin structures endow them with ultrahigh surface-to-volume ratios, making it possible to expose great proportions of coordinatively unsaturated metal atoms at surface and edges which may become active centers to enhance catalyzing reaction.[23] The full exposure of active sites makes them readily functionalized, which is beneficial to enhance their stability, electronic structures, physicochemical properties, and thus final catalytic performance.[5,24] Compared with the non-metal elemental X-enes (e.g., phosphorene, silicone, and borophene), the large specific surface areas and improved surface energy of metal atoms can greatly promote the adsorption of reactants.[25] The higher connectivity of atoms can significantly reduce the charge

61 transfer distances, thus accelerating charge transfer during electrocatalysis process.[26] Metallenes

62 can be formed in a freestanding format without supports, enabling their flexible applications.[27]

63 Considering all above issues, the combination of Pd-based transition metal alloys and transition

64 metal metallenes may be a strategy to solve the problems of high cost and poor durability of Pd-

65 based catalysts for MOR.

66   Herein, a novel 2D heterostructure of NiCoPd inlaid NiCo-bimetallene (NiCoPd/NiCo-

67 bimetallene) has been designed and synthesized through structure directing effect of 18-crown-6

68 ether under under ultrasonic-pulse interface together with HCHO reduction and atom-diffusion-

69 aging process. The constructed NiCo-bimetallene can maximize the accessible surface areas,

70 which facilitates the electrode/electrolyte contact and guarantees a high ion transfer and effective

71 electron delivery in electrochemical catalytic reaction system. The HCHO reduction and atom-

72 diffusion-aging process in the solvothermal system results in NiCoPd ternary-alloy are embedded

73 in NiCo-bimetallene. In the case, Pd active sites in the NiCoPd ternary-alloy can be well dispersed

74 on the surface of NiCo-bimetallene rather than in the interior, thus the availability of Pd sites can

75 be substantially increased. In virtue of the enhanced intrinsic activity via the 'bifunctional

76 mechanism', i.e. the adsorption of NiCo-bimetallene for intermediate species and the increased Pd

77 active site. Moreover, the anti-CO poisoning ability can be optimized through 'alloying ligand

78 effect' of NiCoPd ternary-alloy, since the electronic structure of Pd is adjusted to reduce the

79 affinity of intermediate species. All above advantages enable the designed NiCoPd/NiCo-

80 bimetallene to exhibit excellent catalytic performance for MOR with mass activity of 861

81 mA/mg$_{Pd}$, which is better than that of commercial Pd/C electrocatalyst. Meanwhile, the catalytic

82 activity can be maintained after 4500 s. This design strategy and proposed material structure

83 affords an approach to new efficient catalyst.

84 **2. Experimental Section**

85 2.1 Synthesis of NiCo-bimetallene

86   The NiCo-bimetallene was synthesized using two-phase solution method. The typical synthesis

87 process is described as follows. $CoCl_2 \cdot 6H_2O$ pentanol solution (75 mL, 5 mM) and $NiCl_2 \cdot 6H_2O$

88 aqueous solution (25 mL, 5 mM) were mixed to form two-phase interfaces of pentanol and aqueous

89 solution. Then $NaBH_4$ (10 mL, 3 *wt*.%) aqueous solution containing 18-crown-6 ether (1 g) was

90 slowly added into the above two-phase interface under ultrasonic agitation. After 120 min reaction,

91 the product of NiCo-bimetallene was collected at two-phase interface. It should be noted that N_2

92 gas has been continuously introduced for protection during the whole synthesis process.

93 2.2 Synthesis of NiCoPd/NiCo-bimetallene

94 3 mL of as-obtained NiCo-bimetallene was added into EG (10 mL) solution. Then H_2PdCl_4

95 solution (1 mL, 5 mM) and HCHO (40%, 100 μL) were added into the above solution. The mixed

96 solution was transferred to the autoclave and heated. Finally, powders were recovered, rinsed, and

97 dried.

98 2.3 Characterization

99 Field-emission scanning electron microscope (FE-SEM, S-4800, Japan) was used to investigate

100 the morphology of the samples, and elemental compositions were analyzed using an energy

101 dispersive X-ray spectroscope (EDS), which was conducted at 20 keV on a TN5400 EDS

102 instrument (Oxford). Microstructures of the materials were studied using a high-resolution

103 transmission electron microscope (HR-TEM, JEM-2100EX, Japan). Spherical aberration

104 corrected transmission electron microscope (AC-TEM, JEM ARM 200F, Japan) was used to

105 measure HADDF image of element mapping under an accelerating voltage of 200 kV. Powder X-

106 ray diffraction (XRD) patterns were obtained using a Bruker D8 (German) X-ray diffractometer

107 with a Cu Kαradiation source (λ = 0.1541 nm) and a scanning angle (2θ) of 30°-80°, operated at

108 40 kV and 40 mA. Chemical states of elements were analyzed using an X-ray photoelectron

109 spectroscope (XPS, RBD-upgraded PHI-5000C ESCA system, Perkin Elmer) with a Mg Kα

110 radiation (hv = 1486.6 eV). Before analyzing the XPS peaks, the binding energies of all the

111 elements were calibrated using the containment carbon (C1s = 284.6 eV) as the reference.

112 Deconvolution of the XPS spectra was performed after subtracting the background of each peak

113 using the Shirley function.

114 2.4 Electrochemical measurements

115 Electrocatalytic performance of the as-prepared products was evaluated using a CHI 601E

116 electro-chemistry workstation (Shanghai, China) with a three-electrode cell. Then, 5 μL of the 4

117 mg$\cdot$mL^{-1} catalyst suspension was dropped on the glass carbon electrode. After the electrode was

118 thoroughly dried, 1 μL of a 0.5 wt.% Nafion solution was cast onto the electrode surface to maintain

119 the stability of the catalysts. Cyclic voltammetry (CV) measurements were performed in scan

120   range from 0 to -1 V *vs*. Hg/HgO at a sweep rate of 50 mV·s^{-1} in a nitrogen-saturated solution of

121   0.5 M KOH and 0.5 M KOH + 0.5 M methanol. The chronoamperometric curves were measured

122   at constant potential of -0.2 V *vs*. Hg/HgO for 20000 s. The accelerated cycling tests were

123   conducted for 500 cycles. For comparison, the commercial Pd/C catalyst (40 *wt*.%) was used as

124   the benchmark, and the same procedure as described above was applied to conduct the

125   electrochemical measurements.

126   **3. Results and Discussion**

127   3.1 Design and fabrication
128
129   **Figure 1.** Synthesis schematic view of NiCoPd/NiCo-bimetallene.

130   A schematic view for the synthesis of NiCoPd/NiCo-bimetallene is illustrated in Figure 1. 18-

131   crown-6 ether is selected as the structure directing agent for the construction of 2D NiCo-

132   bimetallene. 18-crown-6 ether can shuttle continuously between pentanol and aqueous solution

133   under the action of ultrasound agitation because it is a macrocyclic molecule containing

134   hydrophilic ether groups and hydrophobic alkyl chains,[28] which makes the primary 18-crown-6

135   ether coordination complex of Ni(II)&Co(II) form at the interface of two-phase solution.[29,30] Since

136   there are lone pair electrons in the ether oxygen of 18-crown-6 ether molecule, this primary

137   complex may show a 2D arrangement at the two-phase interface.[31,32] With the subsequent

138   dropwise addition of reducing agent of NaBH$_4$ aqueous, the primary 18-crown-6 ether

139   coordination complex of Ni(II)&Co(II) is destroyed, which makes the metal ions released slowly

140   and continuously. Under the synergistic effect of ultrasonic induced aggregation,[33] the reduced

141 metal atoms can still be arranged in two-dimensional space and alloyed with the help of high-

142 energy pulse energy. Thus, the formation of 2D bimetallene structure is promoted (Figures S1-2).

143 In the continuously solvothermal reaction process, Pd ions are slowly reduced by HCHO.

144 Simultaneously, the lone pair electrons on oxygen in EG can act as a linker, which leads to the

145 reduced Pd being adsorbed on the surface of NiCo-bimetallene. Further, the reduced Pd undergo

146 uniformly slow atom-diffusion process and long-time aging treatment to form NiCoPd/NiCo-

147 bimetallene finally.[34-36]

148 3.2. Morphologies and structures
149

150 **Figure 2.** The SEM (a), TEM (b), AFM (c), HRTEM (d) images, SADP pattern (e), HADDF

151 image (f) with element mapping (g-i) of NiCoPd/NiCo-bimetallene.

152 Figure 2 shows the morphology and structure of NiCoPd/NiCo-bimetallene. The SEM and TEM

153 images reveal that the synthesized NiCoPd/NiCo-bimetallene has a 2D ultrathin structure within

154 the NiCoPd ternary-alloy inlaid NiCo-bimetallene (Figures 2a-b). The thickness can be obtained

155 from the AFM analysis, which is shown in Figure 2c. Compared with NiCo-bimetallene with

156 thickness of 0.9 nm (Figures S3a-c), NiCoPd/NiCo-bimetallene has a much larger thicker

157 thickness of 1.45 nm, mainly due to the diffusion of Pd into NiCo alloy in bimetallene to form

158 NiCoPd ternary-alloy. In Figure 2d, the HRTEM image shows three different lattice spacings of

159 0.183, 0.197, and 0.245 nm, corresponding to NiCo (111), NiCo (200), and NiCoPd (111) planes,

160 respectively. SADP pattern also confirms the formation heterostructures of NiCoPd inlaid NiCo-

161 bimetallene, which can be revealed by the polycrystalline diffraction rings of (111) & (200) planes

162 of NiCo and (111) plane of NiCoPd (Figure 2e). There are two obvious changes which can be

163 observed compared with NiCo-bimetallene which only shows NiCo (111) plane with a lattice

164 spacing of 0.183 nm (Figure S3d). The elemental distributions of NiCoPd/NiCo-bimetallene were

165 revealed by the HAADF-STEM-EDS mappings, where the combined (Figure 2f), Ni (Figure 2g),

166 Co (Figure 2h), and Pd (Figure 2i) images reveal that Ni and Co elements are mainly uniform

167 distributed, whereas distribution of Pd element is relatively concentrated due to the formation of

168 NiCoPd ternary-alloy. Pd doesn't appear in the pure NiCo-bimetallene (Figure S4). We can

169 confirm that the NiCoPd/NiCo-bimetallene heterostructure can be well achieved.

170　　Figure 3a shows the XRD pattern of NiCo-bimetallene, which reveal the diffraction peaks at

171 44.3°, 51.6°, and 76.0°, corresponding to (111), (200), and (220) lattice planes (Ni-PDF#: 65-0380

172 and Co-PDF#: 15-0806). Obviously, the diffraction peaks of (111), (200), and (220) lattice planes

173 are shifted to 42.4°, 49.4°, and 72.1° when the NiCoPd ternary-alloy are produced by HCHO

174 reduction process and atom-diffusion-aging in the solvothermal system. These peaks are located

175 between those of NiCo alloy and crystal Pd (PDF#: 65-6714), confirming the formation of NiCoPd

176 ternary-alloy. EDS analysis confirms that Pd exists in the NiCoPd/NiCo-bimetallene but is absent

177 in NiCo-bimetallene, which is consist with the above XRD results (Figure 3b). XPS results are

178 used to provide evidence for the reconfiguration of electron structure of NiCoPd/NiCo-

179 bimetallene. The survey spectrum of NiCoPd/NiCo-bimetallene reveals peaks of Ni 2p, Co 2p,

180 and Pd 3d (Figure 3c). The high-resolution XPS spectrum of Ni 2p is shown in Figure 3d. After

181 the HCHO reduction and atom-diffusion-aging process, the binding energy shows Ni^0 in NiCo-

182 bimetallene is shifted to high binding energy (~1.1 eV) from 852.3 and 870.3 eV to 853.4 and

183 871.3 eV for Ni $2p_{3/2}$ and Ni $2p_{1/2}$, respectively.[37,38] The similar shifts for Co 2p (~0.9 eV), which

184 are from 778.40 to 779.30 eV (Co $2p_{3/2}$) and from 794.00 to 794.9 eV (Co $2p_{1/2}$) (Figure 3e).[37,38]

185 However, for the characteristic peaks of Pd 3d in NiCoPd/NiCo-bimetallene shift toward a lower

186 binding energy side with a value of ~ 0.80 eV, e.g., from 334.90 to 334.1 eV (Pd $3d_{5/2}$), and from

187 340.10 eV to 339.30 eV (Pd $3d_{3/2}$) (Figure 3f).[39,40] The reason for the above phenomenon is that

188 the different electronegativities of the metals lead to effective electron transfer between metals in

189 the alloy system, which results in the shift of the binding energy peak position in the XPS spectra.

190 The characteristic peaks shift to higher binding energy orientations when the metals donate

191 electrons to the others, whereas they would shift to a lower orientation when receiving electrons.[41]

192　When the atom-diffusion-aging is finally carried out to form NiCoPd ternary-alloy, Pd receives
193　electrons from Ni and Co, which leads to the left-shift. The observed changing trends of XPS peaks
194　are consistent with the prediction ones from HRTEM and XRD analysis results. All these prove
195　the formation of NiCoPd/NiCo-bimetallene.
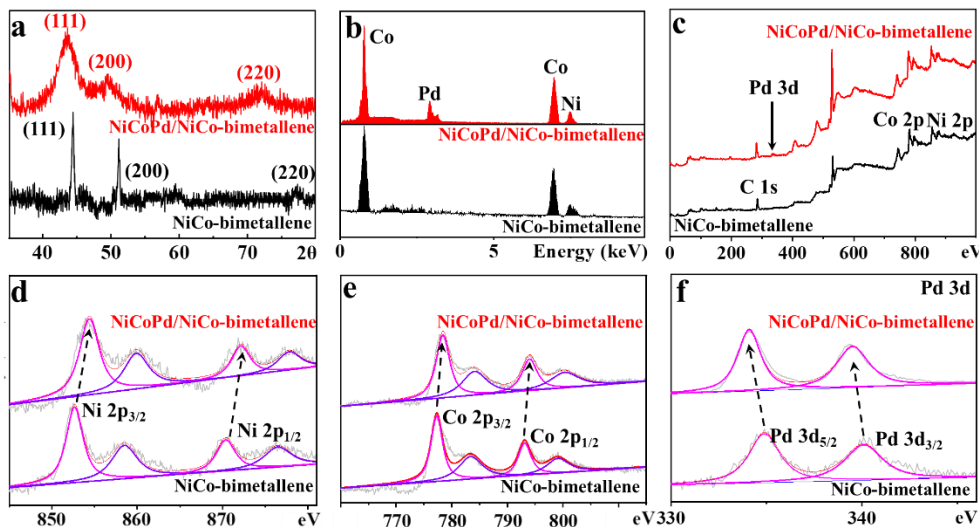

196

197　**Figure 3.** XRD patterns (a), EDS spectra (b), Full XPS survey spectra scans (c), and element detail
198　XPS spectra (d-f) of NiCoPd/NiCo-bimetallene and NiCo-bimetallene, respectively.

199　3.3. Catalytic activity of MOR

200　　MOR in an alkaline media is selected as the probe reaction to investigate the catalytic
201　performance of NiCoPd/NiCo-bimetallene. In contrast to the acid environment, an alkaline media
202　can provide a less corrosive environment to the catalysts,[42] and the abundant OH^- in the alkaline
203　media provide the sources of OH_{ads}, thus improving the reaction speed of the oxidation step of
204　methanol and CO intermediates.[43,44] The catalytic performance of MOR is evaluated via assessing
205　its mass activity, electrochemical active surface area (EASA), anti-CO poisoning ability, and
206　stability. Considering that the importance of active Pd distribution in formed NiCoPd ternary-alloy
207　is affected by aging time and temperature, these two parameters are investigated first. In the
208　solution of 0.5 M KOH + 0.5 M methanol at 25°C, CV curves of NiCoPd/NiCo-bimetallene
209　obtained in different atom-diffusion-aging times (Figure 4a) and temperatures (Figure 4b) are quite
210　similar and both display two characteristic anodic (oxidation) current peaks. The oxidation peak
211　in the forward scan is corresponding to the oxidation of freshly chemisorbed species coming from
212　methanol adsorption, meanwhile the reverse oxidation peak is primarily associated with the
213　removal of incompletely oxidized carbonaceous species (e.g., CO, HCOO, etc.) in the forward

214 scan.[45] For comparisons of electrochemical activity, Table 1 lists the values of the forward and
215 reverse oxidation current peaks for MOR.

216 **Table 1.** Information of electrocatalytic activity by NiCoPd/NiCo-bimetallene toward MOR.

Materials		Forward sweep	Reverse sweep	I_f/I_b	EASA

NiCo-bimetallene		224	161	1.39	——
Commercial Pd/C		450	611	0.74	58.6
Figure 4. CV curves of the prepared samples obtained in different conditions (sweep rate of 50 mV·s^{-1} in 0.5 M KOH + 0.5 M methanol solution): atom-diffusion-aging times (a) and temperatures (b), comparison materials (c).
It is clearly seen that the NiCoPd/NiCo-bimetallene shows a much higher catalytic activity than that of NiCo-bimetallene (non-aging treatment), indicating the electrocatalytic activity attributed to NiCoPd nanophase. In addition, the mass activity of NiCoPd/NiCo-bimetallene for MOR exhibits substantial changes under different atom-diffusion-aging conditions. The mass activity reaches a maximum value of 861 mA/mg$_{Pd}$ under 150°C for 48 h, which shows its larger value compared with that of the commercial Pt/C catalyst (i.e., 450 mA/mg$_{Pd}$). This is mainly attributed to the influence of atom-diffusion-aging treatment on the EASA. To verify this, the EASA of the electrodes are calculated by the following equation:[46]

$$EASA = Q/(405 \times [Pd]) \tag{1}$$

where [Pd] represents the Pd loading (mg/cm^2). The determining the coulombic charge (Q) corresponds to the reduction peak of palladium oxide in CV curves of sample in 0.5 M KOH solution.[47] A charge value of 405 μC/cm^2 is assumed for the reduction of PdO monolayer.[48]

In the process of aging treatment, the influencing factors of EASA depend on the morphology of 2D structure of NiCo-bimetallene and alloying degree of NiCoPd. As expected, the calculation results of EASA based on the Figure S5 show that the maximum EASA value (185.2 m^2/g Pd) can be obtained by the atom-diffusion-aging treatment under 150°C for 48 h, which is corresponding to the conditions for the optimal mass activity (Table 1). In theory, the degree of atomic interdiffusion has been enhanced when the temperature and duration are increased, which is conducive to the alloying of reduced Pd and NiCo-bimetallene. However, the EASA value does not increase but it becomes decreased with the increase of atom-diffusion-aging treatment time and temperature. There are two reasons to this phenomenon. The first one is that the agglomeration

10

242 of 2D bimetallene structure leads to the decrease of EASA and the number of active sites (Figures
243 S6 and S7). The second one is that the excessive atom-diffusion-aging treatment causes migration
244 of some platinum atoms into the interior of NiCo-bimetallene rather than staying at the surface.
245 Therefore, these platinum atoms are no longer the catalytic active centers, thus resulting in the
246 decrease of ECSA. As a higher EASA value is the key to ensure a higher mass activity, therefore,
247 the mass activity of optimized NiCoPd/NiCo-bimetallene is much higher than that of the
248 commercial Pd/C (450 mA/mg$_{Pd}$) due to its larger EASA (Figures 4c and S8, Table1). Compared
249 to Pd/C, the anti-CO poisoning ability of NiCoPd/NiCo-bimetallene in the process of catalytic
250 MOR is enhanced by the 'bifunctional mechanism'. Specifically, the NiCo-bimetallene can
251 facilitate the oxidation process and the removal of the CO intermediates adsorbed onto the NiCoPd
252 ternary-alloy active sites by adsorbing hydroxide (OH^-) species.[49] Consequently, more NiCoPd
253 ternary-alloy active sites become accessible for the MOR, thereby enhancing catalytic
254 performance to obtain a higher mass activity.[50] In the process of MOR, large numbers of CO
255 intermediates (CO_{ads}) have been produced, and then adsorbed on the surfaces of the catalyst. They
256 occupy the active sites, thus causing the inactivation or partially inactivation of catalyst.[51] The
257 anti-CO poisoning ability of catalyst is an important part of evaluating the catalytic activity and
258 catalytic efficiency.[52] The ratio of the forward oxidation current density (I_f) to the reverse oxidation
259 current density (I_b), (I_f/I_b), can be used to describe the anti-CO poisoning ability of the catalyst.[53]
260 A high I_f/I_b ratio suggests efficient electrooxidation of methanol during the forward scan and less
261 accumulation of residues on the electrodes, whereas a low ratio indicates incomplete
262 electrooxidation of methanol and excessive accumulation of carbonaceous residues on the
263 electrode surface.[53-55] According to Table 1, the values of I_f/I_b for all the NiCoPd/NiCo-bimetallene
264 are higher than that of commercial Pd/C, which proves their excellent anti-CO poisoning ability.
265 The electrochemical reactions are listed as follows:

$$NiCoPd + CH_3OH + 4OH^- \rightarrow CO_{ads}\text{-}NiCoPd\text{-}CO_{ads} + 4H_2O + 4e^- \tag{2}$$

$$NiCo + OH^- \rightarrow OH_{ads}\text{-}NiCo\text{-}OH_{ads} + e^- \tag{3}$$

$$CO_{ads}\text{-}NiCoPd\text{-}CO_{ads} + OH_{ads}\text{-}NiCo\text{-}OH_{ads} \rightarrow (COOH)_{ads}\text{-}NiCoPd\text{-}(COOH)_{ads} + NiCo \tag{4}$$

$$(COOH)_{ads}\text{-}NiCoPd\text{-}(COOH)_{ads} + OH^- \rightarrow NiCoPd + CO_2\uparrow + H_2O + e^- \tag{5}$$

270 It is clear from the above MOR process that NiCoPd is the main MOR catalytic active site.
271 Methanol is oxidized to CO_{ads} after adsorption. Subsequently, the adsorbed OH species by NiCo-
272 bimetallic around the NiCoPd can promote the further oxidation of CO_{ads} to the final product CO_2

273 at the NiCoPd active site, as shown in Figure 5a. Theoretically, adsorbed CO intermediates bind

274 strongly to the Pd sites,[34] but for NiCoPd ternary-alloy, the inherent structural coupling between

275 the NiCo lattice and the Pd lattice generates a compression strain of the Pd lattice, mainly due to

276 the shorter interatomic distance of the NiCo sites as compared with that of Pd. Therefore, this so-

277 called 'alloying ligand effect' increases the d-orbital overlap, contributing to a down-shift in

278 energy for the weighted center of the d-band.[56] In essence, electron density is withdrawn from the

279 Pd d-band towards that of the dopant metals. In terms of practical consequences for catalysis, both

280 the lower weighted center of the d-band and the reduced electron density collectively contribute

281 to a lowered CO affinity as a result of a concomitant weakening of the overlap between the Pd d-

282 orbitals and the CO π^*-orbitals.[57] Hence, CO coverage is effectively reduced, which

283 correspondingly increases the number of exposed Pd active sites available for the MOR. In terms

284 of the influence of Ni:Co mass ratio (Figure 5b), the reported DFT calculations[58] had been certified

285 that the adsorption energies (E_{ads}) of methanol on the Ni sites is higher than that of on the Co sites,

286 which shows the preferential adsorption of methanol molecules on the Ni sites. The higher values

287 of E_{ads} imply a higher degree of methanol poisoning. On the other hand, the adsorption energy of

288 CO on Ni sites is also higher than that on the Co sites, which results in a higher CO poisoning on

289 that on the Ni sites. For the influence of Pd mass ratio (Figure 5c), the mass activity of MOR is

290 gradually increased with the increase of the mass ratio of Pd. It is worth noting that this ratio is

291 unable to increase indefinitely. When the ratio is increased to 15%, the value of I_f/I_b is decreased

292 rapidly to 0.91, indicating the decline of the anti-CO poisoning ability of the catalyst. Therefore,

293 the maximum EASA value and optimal mass activity are obtained when the mass ratio of Ni:Co:Pd

294 in NiCoPd/NiCo-bimetallene is 27:63:10 (Figure S9).

295   The catalytic stability is a crucial index for a comprehensive evaluation of the electrocatalyst

296 for a fuel cell. In this work, the following two aspects are discussed about its the stability, i.e., the

297 retention current after chronoamperometry test, and the structural stability after 500 CV cycles.

298 Results indicate that the as-prepared NiCoPd/NiCo-bimetallene show a better desirable stability in

299 each of the above two aspects. Figure 5d illustrates the chronoamperometric curves at a constant

300 potential of -0.2 V *vs*. Hg/HgO for 20000 s. During this period, the optimized NiCoPd/NiCo-

301 bimetallene retains a maximum of 454.6 mA/mg$_{Pd}$ until the stability is reached. This result is

302 superior to the known metallenes (Table S1). This value is much higher than those of NiCo-

303 bimetallene and commercial Pd/C. Figure 5e compares the mass activities of optimized

NiCoPd/NiCo-bimetallene before and after 500 CV cycles, which shows that the mass activity of the one after 500 CV cycles decreases by about 50%, the I_f/I_b value is close to 1, and the morphology of 2D bimetallene is also changed significantly. This may be due to the irreversible phase transformation of the alloy phase caused by the adsorption of intermediate species in the MOR process (Figure S10). This results in the weakened bonding energy of NiCoPd/NiCo-bimetallene, therefore, it is difficult to maintain the metallene structure.[59,60]
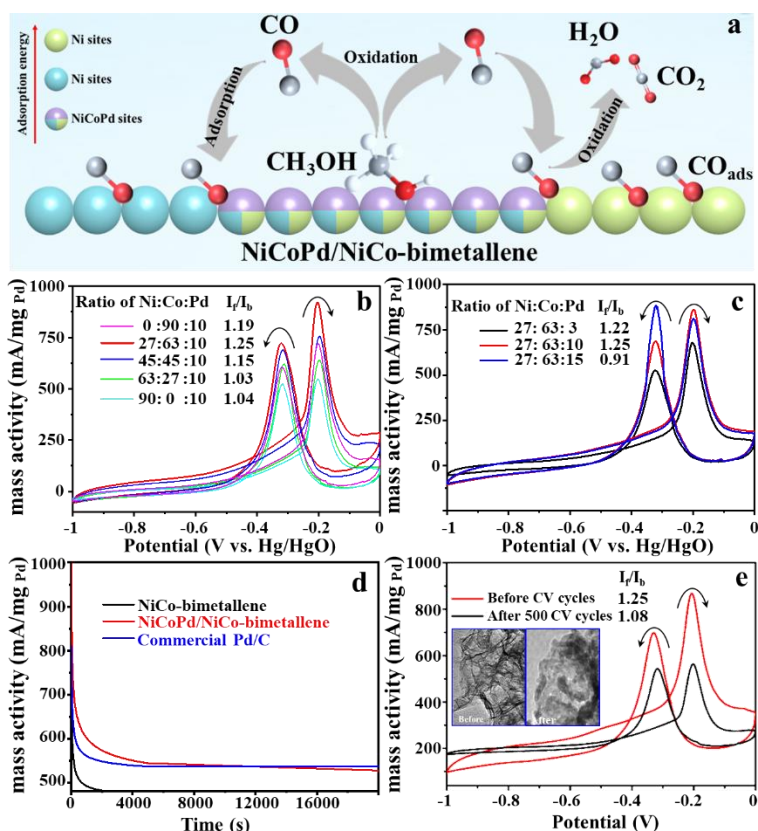

Figure 5. Schematic diagram of MOR electrocatalytic mechanism NiCoPd/NiCo-bimetallene catalyzed (a), CV curves of Ni:Co:Pd mass ratio (b-c) at sweep rate of 50 mV·s^{-1} in 0.5 M KOH + 0.5 M methanol solution, stability tested using chronopotentiometry (d), mass activity (e, TEM images illustration) of before and after CV cyclic.

4. Conclusion

In summary, based on the structure directing effect of 18-crown-6 ether under ultrasonic-pulse interface together with the HCHO reduction and atom-diffusion-aging process in solvothermal system, a novel 2D heterostructure of NiCoPd/NiCo-bimetallene has been successfully synthesized. The MOR is selected to verify the electrocatalytic activities of NiCoPd/NiCo-

bimetallene. The intrinsic activity and anti-CO poisoning ability can be remarkably enhanced via the 'bifunctional mechanism' and 'alloying ligand effect' between inlaid NiCoPd tenary-alloy nanophase and NiCo-bimetallene. By virtue of the maximize utilization of Pd active sites on NiCo-bimetallene, the optimized NiCoPd/NiCo-bimetallene with Ni:Co:Pd ratio of 27:63:10 exhibits excellent catalytic performance, which is better than commercial Pd/C electrocatalyst. This work explores the new way approach to the ternary-alloy included metallene for high efficiency catalysis system toward MOR in DMFC and others.
