Abstract—This paper presents practical design of a three port feed network for a dual-band and dual-polarized patch antenna operating at 1.9 GHz and 2.4 GHz. Initially, design graphs are used to determine the dimensions of the patch for dual band application and the component values of the two equivalent parallel tuned circuits of the antenna at each frequency. Finally the predicted and practical results are compared.

Index Terms—Transmission lines, Microstrip lines, patch antenna, three port network, dual frequency matching, microwave software,

I. INTRODUCTION

There has been tremendous growth of mobile users; Wireless communication device such as mobile requires Bluetooth, GPS embedded into the mobile phones. There is an increasing demand for multi-band antennas that can be easily integrated with the rest of the system. These systems often require compact antennas. The microstrip antennas, which have features of light weight, low cost, and a conformal structure that can be integrated on the same board with the matching network and RF modules, becomes a popular choice [1]

Various design configurations such as probe feed, H shaped, rectangular microstrip antenna exist for dual frequency Microstrip patch antenna has been presented in the literature. [2, 3] presents probe fed dual frequency patch antennas. Single probe-fed rectangular microstrip patch antenna for dual and multi frequency operation has been presented in [2, 4]. A novel closed-form expression for edge extension in predicting of resonant frequency of rectangular microstrip antenna is presented in [3]. H-shaped microstrip antenna of two microstrip dipoles, which resonate at the antenna’s two operating frequencies, has been investigated in [2] This paper presents complete design/matching solution for the dual frequency microstrip patch antenna operating at 1.9GHz (used in PCS mobile applications) and 2.4GHz (used in Bluetooth application). The antenna must have a single feed so that it can be used for either of the above applications. The required return loss at each frequency is 15db [5-8]. Initially a design graph is used to determine the dimensions of the antenna. Then two other design graphs are used (for the input impedance and the ‘Q’ factor of the antenna) to obtain the component values of the two equivalent parallel tuned circuits at the two frequencies. Based on these results the three port feed network and the dual-band antenna is designed and modeled. Finally simulation and manufactured antenna results have been presented.
The theory of patch antennas and the transmission line model [9] are covered. For each design frequency the transmission model of the rectangular patch antenna is simplified to a parallel tuned circuit as shown in Fig.2. The dimensions of the patch and the component values of the parallel tuned circuits are obtained using the design graphs shown in Fig. 3 & 4.

1) The impedance of a high Q parallel tuned circuit is high at resonance and as the frequency changes away from the resonant position the impedance reduces rapidly and consequently power can only radiate at the two specified frequencies.

Fig.2 Transmission Line and Parallel Equivalent Circuits of the patch antenna

The dimensions of the patch and the component values of the equivalent parallel tuned circuits for each frequency are obtained using Figs. 3-5 produced using ‘Advanced Design System’ (ADS) . These results have been derived through simulations.

Fig.3 Physical length of the antenna n the frequency range 1-3 GHz

The two dimensions L1 (at 1.9 GHz) and L2 (at 2.4GHz) are obtained from Fig.3 while the corresponding Q factors and the edge impedance of the patch are obtained from Figs. 4 and 5. The edge impedances and the Q factors are then used to obtain the values of the reactive components for the two parallel tuned circuits.

III. DESIGN THE FEED MATCHING NETWORK

The feed matching network and the equivalent circuits of the antenna at the two frequencies are shown in Fig. 6.

In the design of the feed network the following fundamental properties of parallel tuned circuits and transmission lines are used.

2) For a finite length of a transmission line terminated by a load impedance equal to the line’s characteristic
impedance, the input impedance is constant and independent of the line’s length.

3). It is possible to produce an open circuit at the junction of two lines of finite lengths connected in parallel, one terminated by an open circuit and the other by a short circuit.

The first step in the design of the feed network is to obtain the characteristic impedances of the two quarter wavelength transformers $M_1$ and $M_2$ to match the antenna two edge impedances to $Z_0 (50\ \Omega)$.

At 1.9 GHz the line $M_2$ in Fig. 7(a) is assumed to be effectively terminated by a short circuit and, together with the open circuit stub, produces an open circuit at the feed point so that all power is fed to the 1.9 GHz parallel tuned circuit. The input impedance $Z_{IN1}$ looking into the line $M_4$ in cascade with line $M_2$ is given by equation (1) where all the variables are known except for $\theta_4$ and consequently $Z_{IN1}$ is only a function $\theta_4$.

$$Z_{IN1} = jZ_0 \left( \frac{Z_0 \tan \theta_4 + Z_0 \tan \theta_4}{Z_0 - Z_0 \tan \theta_2 \tan \theta_4} \right) \quad \ldots \ldots \quad (1)$$

Similarly at 2.4 GHz the circuit shown in Fig. 7(b) produces an open circuit so that all power is fed to the antenna. Again it is assumed that $M_1$ is terminated by a short circuit.

The input impedance $Z_{IN2}$ of the line $M_3$ connected in cascade with the line $M_1$ is given by equation (2).

$$Z_{IN2} = jZ_0 \left( \frac{Z_1 \tan \theta_1 + Z_0 \tan \theta_4}{Z_0 - Z_0 \tan \theta_2 \tan \theta_4} \right) \quad \ldots \ldots \quad (2)$$

In equation (2) all the variables are known and $Z_{IN2}$ is only a function of $\theta_3$. There is not a unique solution for equations (1) and (2) and the students are required to identify the constraints for $\theta_4$ and $\theta_3$. These constraints include minimizing the coupling between the feed lines and the patch and to ensure that a single port feed can be used at the two frequencies. Based on these constraints it is necessary to assume a value for $\theta_4$ or $\theta_3$.

**IV. COMPARISON OF PREDICTED AND PRACTICAL RESULTS**

The two dimensions, the edge impedances and the Q factors of the patch antenna at 1.9 GHz and 2.4 GHz obtained from Figures 3, 4 and 5 are shown in Table 1 below.

The equivalent parallel tuned circuits at the two modes are obtained and modeled using MWO software. The impedance of the 1.9 GHz tuned circuit is $0.635-j11\ \Omega$ at 2.4 GHz while the impedance of the 2.4 GHz tuned circuit is $0.64+j9.4\ \Omega$ at 1.9GHz. To satisfy the required length constraints of the feed network, for the 1.9 GHz feed and using assuming $\theta = 174^\circ$ and $Z_{IN1} = j157\ \Omega$ using equation (1).

It can be shown using the Smith chart that if the actual impedance of the 2.4 GHz tuned circuit at 1.9GHz is used ($0.64+j9.4\ \Omega$ then $\theta_4=170^\circ$ obtain the same input) impedance, Hence, the short circuit assumption of the tuned circuit is a good approximation. To produce the required open circuit at the feed position, the electrical length of $M5$ is $18^\circ$ at 1.9 GHz.

At 2.4 GHz the input impedance of the open circuit line $M5$ is $-j120\ \Omega$ and using equation (2) the electrical length $\theta_3=145^\circ$ obtained. If the actual impedance ($0.635-j11\ \Omega$) of the 1.9 GHz tuned circuit at 2.4GHz is used then $\theta_3=149^\circ$ The results of the above designs are summarized in Table.2 assuming short circuits are used and in brackets the electrical lengths are for actual impedance values of the tuned circuits.

Table 3 summarizes the dimensions of the microstrip lines using FR4 substrate to realize the feed network shown in Fig. 6. Modeling the designs using MWO software, Fig.8 compares the frequency response for the return loss of the designed antenna using ideal and Microstrip lines. MWO software also has the facility to optimize circuit designs. This was used to optimize the design where microstrip junctions and bends were included. The optimized dimensions of the feed network are given in Table 4.

The frequency response of the return loss obtained from practical measurements, predicted results using MWO and ADS software is compared in Fig.10. There is an excellent agreement between the predicted results using MWO and ADS and a difference of 50 MHz or approximately 2% for the practical results. As the relative permittivity of the PCB substrate at high frequencies is not accurately known and if the effect manufacturing errors are considered, then the accuracy of the obtained practical results is very good.

Fig.11 shows the polar patterns of the antenna at 1.9GHz and 2.4GHz obtained using ADS software where there is an excellent isolation between the two radiated modes. The frequency response of the gain of the antenna shown in Fig.12 was also obtained using ADS software. The gain is zero dB at 1.9 GHz and 2dB at 2.4GHz. The reason for these low gains is due to the high loss tangent of the substrate. If the loss tangent is changed to 0.001, which a typical value for substrates used in microwave designs, then the predicted gains from the ADs software are 3.4 dB (at 1.9GHz) and 3.97 dB (at 2.4 GHz).
Design graphs are used to determine the dimensions of a dual frequency rectangular patch antenna and the circuit components of equivalent parallel tuned circuits for each mode. Then the properties of matched and reactively terminated ideal transmission lines are used to design the required feed network. As there is not a unique solution to the design equations they have to consider other constraints in order to obtain a practical feed network.

The ideal transmission lines are then replaced by Microstrip lines so that their designs can be fabricated and tested. Their designs for both the ideal and Microstrip lines are modeled using AWR Microwave Office software.
