(Dated: March 4, 2009)

Free vibration of a thin-walled laminated composite beam is studied. A general analytical model applicable to the dynamic behavior of a thin-walled composite box section is developed. This model is based on the classical lamination theory, and accounts for the coupling of flexural and torsional modes for arbitrary laminate stacking sequence configuration, i.e. unsymmetric as well as symmetric, and various boundary conditions. A displacement-based one-dimensional finite element model is developed to predict natural frequencies and corresponding vibration modes for a thin-walled composite beam. Equations of motion are derived from the Hamilton’s principle. Numerical results are obtained for thin-walled composites addressing the effects of fiber angle, modulus ratio, and boundary conditions on the vibration frequencies and mode shapes of the composites.

Keywords: Thin-walled composite, classical lamination theory, flexural-torsional vibration

I. INTRODUCTION

Fiber-reinforced composite materials have been used over the past few decades in a variety of structures. Composites have many desirable characteristics, such as high ratio of stiffness and strength to weight, corrosion resistance and magnetic transparency. Thin-walled structural shapes made up of composite materials, which are usually produced by pultrusion, are being increasingly used in many engineering fields. In particular, the use of pultruded composites in civil engineering structures await increased attention.

The theory of thin-walled closed section members made of isotropic materials was first developed by Vlasov [1] and Gjelsvik [2]. Many researchers have shown that thin-walled bars are susceptible to instability in a variety of modes, but a few publications have dealt with dynamic behavior of such members. Closed-form solution for flexural and torsional natural frequencies of isotropic thin-walled bars are found in the literature [3-5]. For composite thin-walled bars, the flexural and torsional vibrations are fully coupled in general even for a doubly symmetric cross-section due to their material anisotropy. Chandra et al. [6] presented a theoretical-cum-experimental study of free vibration characteristics of thin-walled composite box beams with bending-twist and extension-twist coupling under rotating conditions. Song and Librescu [7] focused on the formulation of the dynamic problem of laminated composite thick- and thin-walled, single-cell beams of arbitrary cross-section and on the investigation of their associated free vibration behavior. Armanios and Badir [8] derived the equations of motion for free vibration analysis of anisotropic thin-walled closed-section beams using a variational asymptotic approach and Hamilton’s principle. The analysis is applied two kinds of laminated: the circumferentially uniform stiffness (CUS) and the circumferentially asymmetric stiffness (CAS). Dancila and Armanios [9] used the governing equations provided by Armanios and Badir [8] to isolate the influence of coupling on free vibration of closed-section beams exhibiting extension-twist, bending-twist coupling. Qin and Librescu [10] incorporated non-classical effects such as transverse shear and non-uniformity of membrane shear stiffness in anisotropic thin-walled beams. The solution methodology is based on the Extended Galerkin’s Method and the non-classical effects on the static responses and natural frequencies are investigated. Recently, Cortinez and Piovan [11] presented the stability analysis of composite thin-walled beams with open or closed cross-sections. This model is based on the use of the Hellinger-Reissner principle, that considers shear flexibility in a full form, general cross-section shapes and symmetric balanced or especially orthotropic laminates.

In the present study, the analytical model developed by Lee and Kim [12] and Vo and Lee [13] is extended to the dynamic behavior of a thin-walled composite box beam with doubly symmetric section. This model accounts for the

II. KINEMATICS

The theoretical developments presented in this paper require two sets of coordinate systems which are mutually interrelated. The first coordinate system is the orthogonal Cartesian coordinate system \((x, y, z)\), for which the \(x\) and \(y\) axes lie in the plane of the cross section and the \(z\) axis parallel to the longitudinal axis of the beam. The second coordinate system is the local plate coordinate \((n, s, z)\) as shown in Fig.1, wherein the \(n\) axis is normal to the middle surface of a plate element, the \(s\) axis is tangent to the middle surface and is directed along the contour line of the cross section. The \((n, s, z)\) and \((x, y, z)\) coordinate systems are related through an angle of orientation \(\theta\) as defined in Fig.1. Point \(P\) is called the pole axis, through which the axis parallel to the \(z\) axis is called the pole axis.

To derive the analytical model for a thin-walled composite beam, the following assumptions are made:

1. The contour of the thin wall does not deform in its own plane.
2. The linear shear strain \(\bar{\gamma}_{sz}\) of the middle surface is to have the same distribution in the contour direction as it does in the St. Venant torsion in each element.
3. The Kirchhoff-Love assumption in classical plate theory remains valid for laminated composite thin-walled beams.

According to assumption 1, the midsurface displacement components \(\bar{u}, \bar{v}\) at a point \(A\) in the contour coordinate system can be expressed in terms of a displacements \(U, V\) of the pole \(P\) in the \(x, y\) directions, respectively, and the rotation angle \(\Phi\) about the pole axis,

\[
\bar{u}(s, z) = U(z) \sin \theta(s) - V(z) \cos \theta(s) - \Phi(z) q(s) \tag{1a}
\]

\[
\bar{v}(s, z) = U(z) \cos \theta(s) + V(z) \sin \theta(s) + \Phi(z) r(s) \tag{1b}
\]

These equations apply to the whole contour. The out-of-plane shell displacement \(\bar{w}\) can now be found from the assumption 2. For each element of middle surface, the shear strain become

\[
\bar{\gamma}_{sz} = \frac{\partial \bar{v}}{\partial z} + \frac{\partial \bar{w}}{\partial s} = \Phi'(z) \frac{F(s)}{t(s)} \tag{2}
\]

where \(t(s)\) is thickness of contour box section, \(F(s)\) is the St. Venant circuit shear flow.
After substituting for \( \bar{v} \) from Eq.(1) and considering the following geometric relations,

\[
\begin{align*}
\frac{dx}{ds} &= \cos\theta \\
\frac{dy}{ds} &= \sin\theta
\end{align*}
\]

Eq.(2) can be integrated with respect to \( s \) from the origin to an arbitrary point on the contour,

\[
\bar{w}(s,z) = W(z) - U'(z)x(s) - V'(z)y(s) - \Phi(z)\omega(s)
\]

where differentiation with respect to the axial coordinate \( z \) is denoted by primes ('); \( W \) represents the average axial displacement of the beam in the \( z \) direction; \( x \) and \( y \) are the coordinates of the contour in the \((x,y,z)\) coordinate system; and \( \omega \) is the so-called sectorial coordinate or warping function given by

\[
\omega(s) = \int_{s_0}^{s} \left[ r(s) - \frac{F(s)}{l(s)} \right] ds
\]

where \( r(s) \) is height of a triangle with the base \( ds \); \( A_i \) is the area circumscribed by the contour of the \( i \) circuit. The explicit forms of \( \omega(s) \) and \( F(s) \) for box section are given in Ref.[13].

The displacement components \( u, v, w \) representing the deformation of any generic point on the profile section are given with respect to the midsurface displacements \( \bar{u}, \bar{v}, \bar{w} \) by the assumption 3.

\[
\begin{align*}
u(s,z,n) &= \bar{u}(s,z) \\
v(s,z,n) &= \bar{v}(s,z) - n\frac{\partial \bar{u}(s,z)}{\partial s} \\
w(s,z,n) &= \bar{w}(s,z) - n\frac{\partial \bar{u}(s,z)}{\partial z}
\end{align*}
\]

The strains associated with the small-displacement theory of elasticity are given by

\[
\begin{align*}
\epsilon_s &= \bar{\epsilon}_s + n\bar{\kappa}_s \\
\epsilon_z &= \bar{\epsilon}_z + n\bar{\kappa}_z \\
\gamma_{sz} &= \bar{\gamma}_{sz} + n\bar{\kappa}_{sz}
\end{align*}
\]

where

\[
\begin{align*}
\bar{\epsilon}_s &= \frac{\partial \bar{u}}{\partial s} \\
\bar{\epsilon}_z &= \frac{\partial \bar{w}}{\partial z} \\
\bar{\kappa}_s &= -\frac{\partial^2 \bar{u}}{\partial z^2} \\
\bar{\kappa}_z &= -\frac{\partial^2 \bar{u}}{\partial s \partial z} \\
\bar{\kappa}_{sz} &= -2\bar{\chi}_{sz} = \bar{\kappa}_{sz}
\end{align*}
\]

All the other strains are identically zero. In Eq.(8), \( \bar{\epsilon}_s \) and \( \bar{\kappa}_s \) are assumed to be zero. \( \bar{\epsilon}_z, \bar{\kappa}_z \) and \( \bar{\kappa}_{sz} \) are midsurface axial strain and biaxial curvatures in the shell, respectively. The above shell strains can be converted to beam strain components by substituting Eqs.(1), (4) and (6) into Eq.(8) as

\[
\begin{align*}
\bar{\epsilon}_z &= \epsilon_z^0 + x\kappa_y + y\kappa_x + \omega\kappa_\omega \\
\bar{\kappa}_z &= \kappa_y \sin\theta - \kappa_x \cos\theta - \kappa_\omega q \\
\bar{\kappa}_{sz} &= 2\bar{\chi}_{sz} = \kappa_{sz}
\end{align*}
\]

where \( \epsilon_z^0, \kappa_x, \kappa_y, \kappa_\omega \) and \( \kappa_{sz} \) are axial strain, biaxial curvatures in the \( x \) and \( y \) direction, warping curvature with respect to the shear center, and twisting curvature in the beam, respectively defined as

\[
\begin{align*}
\epsilon_z^0 &= W' \\
\kappa_x &= -V'' \\
\kappa_y &= -U'' \\
\kappa_\omega &= -\Phi'' \\
\kappa_{sz} &= 2\Phi'
\end{align*}
\]

The resulting strains can be obtained from Eqs.(7) and (9) as

\[
\begin{align*}
\epsilon_z &= \epsilon_z^0 + (x + n\sin\theta)\kappa_y + (y - n\cos\theta)\kappa_x + (\omega - nq)\kappa_\omega \\
\gamma_{sz} &= (n + \frac{F}{2t})\kappa_{sz}
\end{align*}
\]
III. VARIATIONAL FORMULATION

Total potential energy of the system is calculated by,

$$\Pi = \frac{1}{2} \int_v (\sigma_z \varepsilon_z + \sigma_{sz} \gamma_{sz}) dv$$

(12)

After substituting Eq.(11) into Eq.(12)

$$\Pi = \frac{1}{2} \int_v \left\{ \sigma_z \left[ \varepsilon_z^0 + (x + n \sin \theta) \kappa_y + (y - n \cos \theta) \kappa_x + (\omega - nq) \kappa_w \right] + \sigma_{sz} \left( n + \frac{F_l}{2l} \right) \kappa_{sz} \right\} dv$$

(13)

The variation of total potential energy can be stated as

$$\delta \Pi = \int_0^l (N_z \delta \varepsilon_z + M_y \delta \kappa_y + M_x \delta \kappa_x + M_\omega \delta \kappa_\omega + M_t \delta \kappa_{sz}) ds$$

(14)

where $N_z, M_x, M_y, M_\omega, M_t$ are axial force, bending moments in the $x$ and $y$ directions, warping moment (bimoment), and torsional moment with respect to the centroid, respectively, defined by integrating over the cross-sectional area $A$ as

$$N_z = \int_A \sigma_z dsdn$$

(15a)

$$M_y = \int_A \sigma_z (x + n \sin \theta) dsdn$$

(15b)

$$M_x = \int_A \sigma_z (y - n \cos \theta) dsdn$$

(15c)

$$M_\omega = \int_A \sigma_z (\omega - nq) dsdn$$

(15d)

$$M_t = \int_A \sigma_{sz} (n + \frac{F_l}{2l}) dsdn$$

(15e)

The kinetic energy of the system is given by

$$T = \frac{1}{2} \int_v \rho (\dot{u}^2 + \dot{v}^2 + \dot{w}^2) dv$$

(16)

where $\rho$ is a density.

The variation of the kinetic energy is expressed by substituting the assumed displacement field into Eq.(16) as

$$\delta T = \int_v \rho \left\{ \dot{U} \delta \dot{U} + \dot{V} \delta \dot{V} + \dot{W} \delta \dot{W} + (q^2 + r^2 + 2rn + n^2) \dot{\Phi} \delta \dot{\Phi} + (\dot{\Phi} \delta \dot{U} + \dot{U} \delta \dot{\Phi}) \left[ n \cos \theta - (y - y_p) \right] \\
+ (\dot{\Phi} \delta \dot{V} + \dot{V} \delta \dot{\Phi}) \left[ n \cos \theta + (x - x_p) \right] \right\} dv$$

(17)

In Eq. (17), the following geometric relations are used (Fig.1)

$$x - x_p = q \cos \theta + r \sin \theta$$

(18a)

$$y - y_p = q \sin \theta - r \cos \theta$$

(18b)

In order to derive the equations of motion, Hamilton’s principle is used

$$\delta \int_{t_1}^{t_2} (T - \Pi) dt = 0$$

(19)

Substituting Eqs.(14) and (17) into Eq.(19), the following weak statement is obtained
FIG. 2 Geometry of thin-walled composite box section

\[\delta T = \int_{t_1}^{t_2} \int_0^1 \left\{ m_0 \dot{W} \delta \dot{W} + \left[ m_0 \dot{U} + (m_c - m_y + m_0 y_p) \Phi \right] \delta \dot{U} + \left[ m_0 \dot{V} + (m_s + m_x - m_0 x_p) \Phi \right] \delta \dot{V} \\
+ \left[ (m_c - m_y + m_0 y_p) \dot{U} + (m_s + m_x - m_0 x_p) \dot{V} + (m_p + m_2 + 2m_0) \Phi \right] \delta \Phi \\
- N_2 \delta W' + M_2 \delta U'' + M_x \delta V'' + M_\omega \delta \Phi'' - M_t \delta \Phi \right\} \, dz \, dt \tag{20}\]

In Eq.(20), \( m_0, m_c, m_p, m_s, m_x, m_y, m_\omega, m_2 \) are inertia coefficients respectively defined by

\[
m_0 = I_0 \int_s ds \tag{21a}
\]
\[
m_c = I_1 \int_s \cos \theta \, ds \tag{21b}
\]
\[
m_p = I_0 \int_s (q^2 + r^2) \, ds \tag{21c}
\]
\[
m_s = I_1 \int_s \sin \theta \, ds \tag{21d}
\]
\[
m_x = I_0 \int_s x \, ds \tag{21e}
\]
\[
m_y = I_0 \int_s y \, ds \tag{21f}
\]
\[
m_\omega = I_1 \int_s r \, ds \tag{21g}
\]
\[
m_2 = I_2 \int_s ds \tag{21h}
\]

where

\[(I_0, I_1, I_2) = \int_n \rho(1, n, n^2) \, dn \tag{22}\]

The explicit expressions of inertia coefficients for composite box section in Fig.2 are given by

\[
m_0 = I_0^1 b_1 + I_0^2 b_2 + I_0^3 b_1 + I_0^4 b_2 \tag{23a}
\]
\[
m_c = I_0^2 b_2 - I_0^4 b_2 \tag{23b}
\]
\[
m_p = I_0^2 \left[ \frac{1}{3} b_1^3 + (-x_1 + x_p)^2 b_1 \right] + I_0^2 \left[ \frac{1}{3} b_2^3 + (-y_2 + y_p)^2 b_2 \right] \tag{23c}
\]
IV. CONSTITUTIVE EQUATIONS

The constitutive equations of a $k^{th}$ orthotropic lamina in the laminate co-ordinate system of box section are given by

$$\left\{ \begin{array}{c} \sigma_z \\ \sigma_{sz} \end{array} \right\}^k = \left[ \begin{array}{cc} Q_{11} & Q_{16} \\ Q_{16} & Q_{55} \end{array} \right] \left\{ \begin{array}{c} \varepsilon_z \\ \gamma_{sz} \end{array} \right\}$$

where $Q_{ij}$ are transformed reduced stiffnesses. The transformed reduced stiffnesses can be calculated from the transformed stiffnesses based on the plane stress assumption and plane strain assumption. More detailed explanation can be found in Ref.[14]

The constitutive equations for bar forces and bar strains are obtained by using Eqs.(11), (15) and (24)

$$\left\{ \begin{array}{c} N_z \\ M_s \\ M_w \\ M_t \end{array} \right\} = \left[ \begin{array}{cccc} E_{11} & E_{12} & E_{13} & E_{14} \\ E_{22} & E_{23} & E_{24} & E_{25} \\ E_{33} & E_{34} & E_{35} & E_{36} \\ E_{44} & E_{45} & E_{46} & E_{55} \end{array} \right] \left\{ \begin{array}{c} \varepsilon_z \\ \kappa_y \\ \kappa_x \\ \kappa_{sz} \end{array} \right\}$$

where $E_{ij}$ are stiffnesses of the thin-walled composite, and can be defined by

$$E_{11} = \int_a^b A_{11}ds$$

$$E_{12} = \int_a^b (A_{11}x + B_{11}\sin \theta)ds$$

$$E_{13} = \int_a^b (A_{11}y - B_{11}\cos \theta)ds$$

$$E_{14} = \int_a^b (A_{11}\omega - B_{11}q)ds$$

$$E_{15} = \int_a^b (A_{16}\frac{F}{2t} + B_{16})ds$$

$$E_{22} = \int_a^b (A_{11}x^2 + 2B_{11}x\sin \theta + D_{11}\sin^2 \theta)ds$$

$$E_{23} = \int_a^b [A_{11}xy + B_{11}(y\sin \theta - x\cos \theta) - D_{11}\sin \theta \cos \theta]ds$$

$$E_{24} = \int_a^b [A_{11}x\omega + B_{11}(\omega\sin \theta - qx) - D_{11}q\sin \theta]ds$$

$$E_{25} = \int_a^b [A_{16}\frac{F}{2t}x + B_{16}(x + \frac{F\sin \theta}{2t}) + D_{16}\sin \theta]ds$$

$$E_{33} = \int_a^b (A_{11}y^2 - 2B_{11}x\cos \theta + D_{11}\cos^2 \theta)ds$$

$$E_{34} = \int_a^b [A_{11}y\omega - B_{11}(\omega \cos \theta + qy) + D_{11}q\cos \theta]ds$$
\[ E_{35} = \int [A_{16} F_{21} y + B_{16}(y - \frac{F \cos \theta}{2t}) - D_{16} \cos \theta] ds \]  
\[ E_{44} = \int (A_{112} \omega^2 - 2B_{11} \omega q + D_{11} q^2) ds \]  
\[ E_{45} = \int [A_{16} F_{21} \omega + B_{16}(\omega - \frac{F q}{2t}) - D_{16} q] ds \]  
\[ E_{55} = \int (A_{66} F_{42}^2 + B_{66} \frac{F^2}{t} + D_{66}) ds \]
where \( A_{ij}, B_{ij} \) and \( D_{ij} \) matrices are extensional, coupling and bending stiffness, respectively, defined by

\[(A_{ij}, B_{ij}, D_{ij}) = \int Q_{ij}(1, n, n^2) dn \]

It appears that the laminate stiffnesses \( E_{ij} \) depend on the cross section of the composites. The explicit forms of them can be calculated for composite box section and given in the Ref.[13].

V. EQUATIONS OF MOTION

The equations of motion of the present study can be obtained by integrating the derivatives of the varied quantities by parts and collecting the coefficients of \( \delta U, \delta V, \delta W \) and \( \delta \Phi \)

\[ N_z' = m_0 \ddot{W} \]  
\[ M_y'' = m_0 \ddot{U} + (m_c - m_y + m_0 y_p) \ddot{\Phi} \]  
\[ M_x'' = m_0 \ddot{V} + (m_s + m_x - m_0 x_p) \ddot{\Phi} \]  
\[ M_y' + 2M_x' = (m_c - m_y + m_0 y_p) \ddot{U} + (m_s + m_x - m_0 x_p) \ddot{V} + (m_p + m_2 + 2m_\omega) \ddot{\Phi} \]

The natural boundary conditions are of the form

\[ \delta W : N_z' \]  
\[ \delta U : M_y'' \]  
\[ \delta U' : M_y \]  
\[ \delta V : M_x' \]  
\[ \delta V' : M_x \]  
\[ \delta \Phi : M_\omega' + 2M_t \]  
\[ \delta \Phi' : M_\omega \]

By substituting Eqs.(10) and (25) into Eq.(28), the explicit form of the governing equations can be expressed with respect to the laminate stiffnesses \( E_{ij} \) as

\[ E_{11} W'' - E_{12} U'' - E_{13} V'' - E_{14} \Phi'' + 2E_{15} \Phi'' = m_0 \ddot{W} \]  
\[ E_{12} W'' - E_{22} U'' - E_{23} V'' - E_{24} \Phi'' + 2E_{25} \Phi'' = m_0 \ddot{U} + (m_c - m_y + m_0 y_p) \ddot{\Phi} \]  
\[ E_{13} W'' - E_{33} U'' - E_{34} V'' - E_{35} \Phi'' + 2E_{35} \Phi'' = m_0 \ddot{V} + (m_s + m_x - m_0 x_p) \ddot{\Phi} \]  
\[ E_{14} W'' + 2E_{15} W'' - E_{24} U'' - 2E_{25} U'' - E_{34} V'' - 2E_{35} \Phi'' + 4E_{35} \Phi'' = (m_c - m_y + m_0 y_p) \ddot{U} + (m_s + m_x - m_0 x_p) \ddot{V} + (m_p + m_2 + 2m_\omega) \ddot{\Phi} \]

Eq.(30) is most general form for flexural, torsional vibration of a thin-walled laminated composite with a box section, and the dependent variables, \( U, V, W \) and \( \Phi \) are fully coupled. If all the coupling effects are neglected and cross section is symmetrical with respect to both \( x- \) and \( y- \) axes, Eq.(30) can be simplified to the uncoupled differential equations as

\[ (EA)_{com} W'' = \rho A \ddot{W} \]  
\[ -(EI_y)_{com} U'' = \rho A \ddot{U} \]  
\[ -(EI_x)_{com} V'' = \rho A \ddot{V} \]  
\[ -(EI_\omega)_{com} \Phi'' + (GJ)_{com} \Phi'' = \rho I_\phi \ddot{\Phi} \]
From above equations, \((EA)_{\text{com}}\) represents axial rigidity, \((EI_x)_{\text{com}}\) and \((EI_y)_{\text{com}}\) represent flexural rigidities with respect to \(x\) and \(y\) axis, \((EI_z)_{\text{com}}\) represents warping rigidity, and \((GJ)_{\text{com}}\), represents torsional rigidity of the thin-walled composite, respectively, written as

\[
\begin{align*}
(EA)_{\text{com}} &= E_{11} \\
(EI_y)_{\text{com}} &= E_{22} \\
(EI_x)_{\text{com}} &= E_{33} \\
(EI_z)_{\text{com}} &= E_{44} \\
(GJ)_{\text{com}} &= 4E_{55}
\end{align*}
\] (32)

In Eq.(31), \(I_p\) denotes the polar moment of inertia. It is well known that the four distinct vibration modes, axial and flexural vibration in the \(x\) and \(y\) direction and torsional vibration, are identified in this case and the corresponding vibration frequencies are given by the orthotropy solution for simply supported boundary conditions [5]

\[
\begin{align*}
\omega_z &= \frac{n\pi}{l} \sqrt{\frac{(EA)_{\text{com}}}{\rho A}} \quad (33a) \\
\omega_x &= \frac{n^2\pi^2}{l^2} \sqrt{\frac{(EI_y)_{\text{com}}}{\rho A}} \quad (33b) \\
\omega_y &= \frac{n^2\pi^2}{l^2} \sqrt{\frac{(EI_x)_{\text{com}}}{\rho A}} \quad (33c) \\
\omega_0 &= \frac{n\pi}{l} \sqrt{\frac{1}{I_p} \left[ \frac{n^2\pi^2}{l^2} EI_{z\text{com}} + (GJ)_{\text{com}} \right]} \quad (33d)
\end{align*}
\]

where \(\omega_z, \omega_x, \omega_y, \omega_0\) are axial and flexural frequencies in the \(x\) and \(y\) direction, and torsional vibration frequency respectively.

VI. FINITE ELEMENT FORMULATION

The present theory for thin-walled composite beams described in the previous section was implemented via a displacement based finite element method. The generalized displacements are expressed over each element as a linear combination of the one-dimensional Lagrange interpolation function \(\Psi_j\) and Hermite-cubic interpolation function \(\psi_j\) associated with node \(j\) and the nodal values

\[
\begin{align*}
W &= \sum_{j=1}^{n} w_j \Psi_j \\
U &= \sum_{j=1}^{n} u_j \psi_j \\
V &= \sum_{j=1}^{n} v_j \psi_j \\
\Phi &= \sum_{j=1}^{n} \phi_j \psi_j
\end{align*}
\] (34)

Substituting these expressions into the weak statement in Eq.(17), the finite element model of a typical element can be expressed as

\[
([K] - \lambda [M]) \{\Delta\} = \{0\} \quad (35)
\]

where \([K]\) is the element stiffness matrix

\[
[K] = \begin{bmatrix}
K_{11} & K_{12} & K_{13} & K_{14} \\
K_{21} & K_{22} & K_{23} & K_{24} \\
K_{31} & K_{32} & K_{33} & K_{34} \\
K_{41} & K_{42} & K_{43} & K_{44}
\end{bmatrix}_{\text{sym.}}
\] (36)
and \([M]\) is the element mass matrix

\[
[M] = \begin{bmatrix}
M_{11} & M_{12} & M_{13} & M_{14} \\
M_{22} & M_{23} & M_{24} & \\
M_{33} & M_{34} & \\
\text{sym.} & M_{44}
\end{bmatrix}
\] (37)

The explicit forms of \([K]\) and \([M]\) are given by

\[
K_{1ij}^{11} = \int_0^l E_{11} \psi_i' \psi_j' dz
\] (38a)

\[
K_{1ij}^{12} = -\int_0^l E_{12} \psi_i' \psi_j'' dz
\] (38b)

\[
K_{1ij}^{13} = -\int_0^l E_{13} \psi_i' \psi_j'' dz
\] (38c)

\[
K_{1ij}^{14} = \int_0^l (2 E_{15} \psi_i' \psi_j' - E_{14} \psi_i' \psi_j') dz
\] (38d)

\[
K_{2ij}^{22} = \int_0^l E_{22} \psi_i'' \psi_j'' dz
\] (38e)

\[
K_{2ij}^{23} = \int_0^l E_{23} \psi_i'' \psi_j'' dz
\] (38f)

\[

All other components are zero. In Eq.(35), \(\{\Delta\}\) is the eigenvector of nodal displacements corresponding to an eigenvalue

\[
\{\Delta\} = \{W \ U \ V \ \Phi\}^T
\] (39)

VII. NUMERICAL EXAMPLES

For verification purpose, a cantilever composite box beam with length \(l = 844.5\) mm, height \(b_1 = 12.838\) mm, width \(b_2 = 23.438\) mm and the thickness \(t = 0.762\) mm with stacking sequences is considered. Plane stress assumption \((\sigma_x = 0)\) is made in the analysis. The following material properties are used (Ref.[9])

\[
E_1 = 142\text{GPa}, \ E_2 = 9.8\text{GPa}, \ G_{12} = 6.0\text{GPa}, \ \nu_{12} = 0.42, \ \rho = 1.445 \times 10^3\text{kg/m}^3
\] (40)
The results using the present analysis are compared with previously available results in Table I. It is seen that the results by the present finite element analysis are in good agreement with the solution in Ref.[6,10] for all cases of lay-ups.

In order to investigate the effects of fiber orientation, modulus ratio, and boundary conditions on the natural frequencies and mode shapes, a thin-walled composite box beam with length $l = 8m$ is considered. The geometry of the box section is shown in Fig.3, and the following engineering constants are used

$$E_1/E_2 = 25, G_{12}/E_2 = 0.6, \nu_{12} = 0.25$$

(41)

For convenience, the following nondimensional natural frequency is used

$$\bar{\omega} = \frac{\omega l^2}{b_1^2 \sqrt{\rho/E_2}}$$

(42)

A simply supported composite beam with the left and right webs are considered as angle-ply laminates $[\theta]/[-\theta]$ and $[-\theta/\theta]$ and the flange laminates are assumed to be unidirectional. The coupling stiffnesses $E_{13}, E_{14}, E_{23}, E_{24}, E_{35}$ are zero, but $E_{25}$ does not vanish due to unsymmetric stacking sequence of the webs. Accordingly, flexural vibration in the $y$-direction is uncoupled, whereas the flexural vibration in the $x$-direction and torsional vibration are coupled. The lowest four nondimensional natural frequencies by the finite element analysis (FEM) and the orthotropy solutions, which neglects the coupling effects of $E_{25}$, from Eqs.(31a)-(31d) for each mode are given in Table.II. For unidirectional fiber direction, the lowest four natural frequencies by the finite element analysis exactly correspond to the first flexural mode in $x$-direction, the first flexural mode in $y$-direction, the second flexural mode in $x$-direction and the torsional mode by the orthotropy solution, respectively. As the fiber angle changes, however, this order is changing. The mode shapes corresponding to the first four lowest frequencies with fiber angle $\theta = 45^\circ$ are illustrated in Figs.4, 5, 6, and 7. It can be seen in Fig.4, 6 and 7 the vibration mode 1, 3 and 4 exhibit double coupling (flexural mode in $x$-direction and torsional mode). Due to the small coupling stiffnesses $E_{25}$, these modes become predominantly flexural $x$-direction mode, with a little contribution from torsion. Therefore, the results by the finite element analysis and orthotropy solution show slight discrepancy in $\omega_1, \omega_3$ and $\omega_4$. Since the vibration mode 2 is pure flexural $y$-direction mode as can be seen in Fig.5, the orthotropy solution and the finite element analysis are identical.

FIG. 4 Mode shapes of the flexural and torsional components for the first mode $\omega_1 = 5.085$ of the composite beams with the fiber angle $45^\circ$ in the webs

The next example is the same as before except that in this case, the top flange and the left web are considered as $[\theta_2]$, while the bottom flange and web are unidirectional. For this stacking sequence, the coupling stiffnesses $E_{14}, E_{15}, E_{23}, E_{25}$ and $E_{35}$ become no more negligibly small. The mode shapes corresponding to the first four lowest frequencies with fiber angle $\theta = 45^\circ$ are illustrated in Figs.8, 9, 10 and 11. Relative measures of flexural displacements and torsional rotation show that all the modes are triply coupled mode (flexural mode in the $x$ and $y$ directions and torsional mode). Since the first and second modes are dominated by flexural mode rather than torsional mode as shown in Figs.8 and 9, the othotropy solution and the finite element analysis solution of mode 1, 2 are slightly different as in Table.III. However, the third and fourth modes show strong coupling as can be seen in Figs.10 and 11. This fact explains as the fiber angle changes, the orthotropy solution and the finite element analysis solution show discrepancy indicating the coupling effects become significant. That is, the orthotropy solution is no longer valid for unsymmetrically laminated beams, and triply coupled flexural-torsional vibration should be considered even for a double symmetric cross-section.

The next example shows the effects of modulus ratio ($E_1/E_2$) of composite beams on the lowest fifth natural frequencies for a simply supported and a cantilever composite beams (Figs.12 and 13). The stacking sequence of the flanges and webs are $[0/90]_s$. For this stacking sequence, all the coupling stiffnesses vanish and thus, the three distinct vibration mode, flexural vibration in the $x$ and $y$ direction and torsional vibration are identified. It is observed that the natural frequencies $\omega_{x1}, \omega_{x2}, \omega_{y1}, \omega_{y2}$ and $\omega_{x2}$ increase with increasing orthotropy ($E_1/E_2$) for both simply supported and cantilever boundary conditions. However, torsional frequency is almost invariant for both boundary conditions. It can be explained from Eqs.(31d), torsional frequency is dominated by torsional rigidity rather than warping rigidity.
FIG. 5 Mode shapes of the flexural components for the second mode $\omega_2 = 14.660$ of the composite beams with the fiber angle 45° in the webs.

FIG. 6 Mode shapes of the flexural and torsional components for the third mode $\omega_3 = 20.339$ of the composite beams with the fiber angle 45° in the webs.

Moreover, effects of warping is negligibly small for box section. As ratio of $E_1/E_2$ changes, the order of the second flexural mode in the $y$-direction, the torsional mode change each other.

VIII. CONCLUDING REMARKS

An analytical model was developed to study the flexural-torsional vibration of a laminated composite box beam. The model is capable of predicting accurate natural frequencies as well as vibration mode shapes for various configuration including boundary conditions, laminate orientation and ratio of elastic moduli of the composite beams. To formulate

the problem, a one-dimensional displacement-based finite element method is employed. All of the possible vibration modes including the flexural mode in the $x$- and $y$-direction and the torsional mode, and fully coupled flexural-torsional mode are included in the analysis. The model presented is found to be appropriate and efficient in analyzing free vibration problem of a thin-walled laminated composite beam.
