3

4 Running head: Effects of experience and opponents on youths

5 **Effects of experience and opponents on the pacing behaviour and 2-km**  
6 **cycling performance of novice youths.**

7

8 Purpose: To study the pacing behaviour and performance of novice youth exercisers in a controlled  
9 laboratory setting.

10 Method: Ten healthy participants (seven male, three female,  $15.8 \pm 1.0$  years) completed four, 2-km trials  
11 on a Velotron cycling ergometer. Visit 1 was a familiarization trial. Visits 2 to 4 involved the following  
12 conditions, in randomized order: no opponent (NO), a virtual opponent (starting slow and finishing fast)  
13 (OP-SLOWFAST), and a virtual opponent (starting fast and finishing slow) (OP-FASTSLOW).  
14 Repeated measurement ANOVAs ( $p < 0.05$ ) were used to examine differences in both pacing behaviour  
15 and also performance related to power output, finishing- and split times, and RPE between the four  
16 successive visits and the three conditions. Expected performance outcome was measured using a  
17 questionnaire.

18 Results: Power output increased ( $F_{3,27}=5.651$ ,  $p=0.004$ ,  $\eta^2_p=0.386$ ) and finishing time decreased  
19 ( $F_{3,27}=9.972$ ,  $p < 0.001$ ,  $\eta^2_p=0.526$ ) between visit 1 and visits 2, 3 and 4. In comparison of the first and  
20 second visit, the difference between expected finish time and actual finishing time decreased by 66.2%,  
21 regardless of condition. The only significant difference observed in RPE score was reported at the 500m  
22 point, where RPE was higher during visit 1 compared to visits 3 and 4, and during visit 2 compared to  
23 visit 4 ( $p < 0.05$ ). No differences in pacing behaviour, performance, or RPE were found between  
24 conditions ( $p > 0.05$ ).

25 Conclusion: Performance was improved by an increase in experience after one visit, parallel with the  
26 ability to anticipate future workload.

## Introduction

Pacing is widely known as the goal-directed distribution of energy over a predetermined exercise task (Edwards & Polman, 2013) and which is a process of decision-making regarding how and when to spend energy (Smits, Pepping, & Hettinga, 2014). This has been shown to be a decisive component of athletic performance in both time-trial (Foster et al., 2003; van Ingen Schenau, De Koning, & De Groot, 1992) and head-to-head events (Edwards, Guy, & Hettinga, 2016; Konings, Noorbergen, Parry, & Hettinga, 2016; Mauger, Neuloh, & Castle, 2012). The outcome of such decision-making involved in pacing is thus defined as pacing behaviour (Smits et al., 2014). Pacing behaviour can be influenced by many aspects including; the perceived level of fatigue throughout the race (De Koning et al., 2011), the competitive environment (Hettinga, Konings, & Pepping, 2017) and sport specific demands (Stoter et al., 2016). Thus far, most research on pacing behaviour has been conducted in adults, and research on the acquisition of the pacing skill and the development of pacing behaviour in youths is surprisingly scarce (Elferink-Gemser & Hettinga, 2017).

44           Although empirical data on pacing behaviour of youths is limited, one study of time-  
45 trial performances in young children (~5-8 year olds) has suggested it is characterised by an  
46 initial all-out use of energy, which thereafter decreases in velocity over the duration of the bout  
47 (Micklewright et al., 2012). Older children (~10 years old) seem to display a more U-shaped  
48 velocity distribution, suggestive of a goal-driven reservation of energy in order to successfully  
49 execute an exercise task (Lambrick, Rowlands, Rowland, & Eston, 2013; Micklewright et al.,  
50 2012). Furthermore, emerging research from both time-trial and head-to-head events appears  
51 to suggest pacing behaviour of youths (12-21 year old) progressively further develops in  
52 complexity towards that of that of adults (Menting, Konings, Elferink-Gemser, & Hettinga,  
53 2019; Wiersma, Stoter, Visscher, Hettinga, & Elferink-Gemser, 2017). The suggested

54 theoretical basis behind this development of pacing behaviour is twofold. First, during  
55 adolescence there are cognitive and physical changes associated with growth and maturation  
56 (Beunen et al., 1992; Blakemore, Burnett, & Dahl, 2010). Second, the gathering of experience  
57 during exercise tasks, for example by means of training or competition, facilitates the  
58 improvement of physical and cognitive performance characteristics. Improvement of  
59 performance characteristics in turn facilitates the development of adequate pacing behaviour  
60 (Elferink-Gemser & Hettinga, 2017). Therefore, it is likely that the development of maturation  
61 of cognitive characteristics mediate the influence of acquired experience on pacing behaviour.  
62 As such, cognitive functions relevant to pacing include a progressively accurate self-assessment  
63 of physical capability aligned with anticipation of future physiological requirements (Hettinga,  
64 De Koning, & Foster, 2009; Reid et al., 2017), meta-cognitive functions (Elferink-Gemser &  
65 Hettinga, 2017) and deductive reasoning (Van Biesen, Hettinga, McCulloch, & Vanlandewijck,  
66 2017). An underdevelopment of these functions may lead to sub-optimal pacing behaviour  
67 (Micklewright et al., 2012; Van Biesen et al., 2017).

68         Recent literature emphasizes the importance of environmental cues in the decision  
69 making process of pacing (Hettinga et al., 2017; Konings & Hettinga, 2018; Smits et al., 2014).  
70 The anticipation and response to environmental cues (e.g., opponents) has been suggested to be  
71 important both in competition and in the development of pacing behaviour (Menting et al.,  
72 2019). The study of Lambrick et al. (2013) showed that when inexperienced children (~10 years  
73 old), performing an 800m running task, were introduced to opponents, their performance  
74 decreased, with no major change in pacing behaviour. The given explanation for this outcome  
75 was the relative inexperience of the children in a competitive environment which clearly  
76 increases with exposure to a variety of competitive situations over the life span.. Interestingly,  
77 when adult athletes were presented with a performance-matched opponent, an improvement in  
78 performance was demonstrated, which may be due to the greater familiarity of adults to

79 competitive environments (Konings, Parkinson, Zijdewind, & Hettinga, 2018; Konings,  
80 Schoenmakers, Walker, & Hettinga, 2016; Williams et al., 2015). Furthermore, it was found  
81 that the pacing behaviour of the opponent influenced that of the participant, as a faster starting  
82 opponent evoked a faster (matched) start in the participants (Konings et al., 2016). Therefore it  
83 would seem the skills that allows an athlete to anticipate, interpret and implement pacing in the  
84 presence of an opponent are developed during adolescence (Menting et al., 2019). However, in  
85 adolescents, who have not yet developed the accurate pacing behaviour of adults, it is  
86 questionable whether performance would be significantly influenced by an opponent to the  
87 same extent to that of adults. It is plausible the primary driver of inexperienced young athletes  
88 is to properly pace an exercise bout with intrinsic development of their self-paced behaviour,  
89 whereas adults who have already developed this pacing skill are more influenced by the  
90 behaviour of those around them.

91         Adolescence seems to be an crucial period in the development of establishing pacing  
92 behaviour. Nonetheless, most research into pacing has been carried out with adults which is  
93 surprising. The scarce research that has investigated the subject of pacing behaviour in youth  
94 athletes thus far consists mainly of the analysis of split times during competition (Dormehl &  
95 Osborough, 2015; Menting et al., 2019; Wiersma et al., 2017). Therefore, an empirical,  
96 laboratory controlled study would offer the opportunity to investigate several factors that shape  
97 pacing behaviour in youths, without the large variation in environmental circumstances that  
98 accompanies measuring athletes in competition. The aims of the current study were therefore  
99 to investigate what characteristics the pacing behaviour of novice youth exercisers exhibited  
100 during exercise, whether or not their performance and behaviour is influenced by experience  
101 gained over successive trials, and if the presence of an opponent influences their pacing  
102 behaviour and performance.

## Methods

### Participants

Ten youth participants (seven males, three females) completed the study (age:  $15.8 \pm 1.0$  years, height:  $1.79 \pm 0.06$ m, body mass:  $62.0 \pm 7.5$  kg). All participants were healthy and moderate to highly active, as assessed by respectively the PAR-Q (Shephard, Thomas, & Weiler, 1991) and the short version of the IPAQ (Dinger, Behrens, & Han, 2006). All participants were active partakers in a variety of sports (dance, gym, soccer). None of the participants had any previous experience in performing a (cycling) time trial. Written informed consent was obtained from the participants and their parents or legal guardians at the start of the first visit. The study was approved by the ethical committee of the local university in accordance to the Declaration of Helsinki.

### Experimental procedures

All participants completed four, 2-km cycling time trials over four visits. At the start of each visit, each were asked two questions about their motivation (“How motivated are you to perform well on the time trial?”) and performance (“How do you think you will perform?”) concerning the upcoming trial, which were scored on a 5-point Likert scale (5: very motivated, 1: not motivated at all; 5: very good, 1: not good at all). Additionally, participants were asked to estimate a finishing time for the upcoming trial, as an indication of their ability to anticipate the workload of the exercise (“In what time do you think you will complete the time trial of 2km?”). The participants were not given information on their performance on any of the trials until after the completion all visits, as the knowledge of a previous performance could influence performance on upcoming trials. Thereafter, participants performed a five minute warm up with the instruction to perform an average power output of 150 Watts for males and 115 Watts for

128 females (Andersen, Henckel, & Saltin, 1987; Bishop, 2003), followed by a five minute inactive  
129 recovery period before the start of the trial.

130 All time trials were performed on a cycling ergometer (Velotron Dynafit, Racermate,  
131 Seattle, USA), which has been shown to be a reliable and valid tool for testing performance and  
132 pacing behaviour (Astorino & Cottrell, 2012; Hettinga, Schoenmakers, & Smit, 2015). Using  
133 the Velotron 3D software, a 2-km track was created which was straight, flat and featured no  
134 wind. During trials, the track was projected on a screen. Participants were portrayed by an on-  
135 screen avatar. During visit 1, a familiarization trial (FAM) was performed. In this trial  
136 participants performed without the presence of an opponent. During two of the remaining three  
137 visits the participants performed a time trial with an opponent operating different race pacing  
138 strategies, and one without an opponent (NO), all in a randomized order. The two styles of  
139 opponent were created individually for each participant on the basis of the performance during  
140 the familiarization trial (Konings et al., 2016). One opponent (OP-SLOWFAST) used a slow  
141 pace (100% of FAM) between 150-1000m and a fast pace (104% of FAM) between 1000m-  
142 2000m. The other opponent (OP-FASTSLOW) adopted a fast pace (104% of FAM) between  
143 150-1000m and a slow pace (100% of FAM) between 1000-2000m. The initial 150m of the  
144 race were used to give the virtual opponents a start that was comparable to that of human  
145 performers. Both opponents had a total race performance which was two percent faster  
146 compared to the FAM to correct for the expected improvement of the participants after the  
147 FAM, based on the increase in performances of unexperienced children and cycling adults  
148 (Konings et al., 2016; Lambrick et al., 2013). During trials with an opponent, two avatars were  
149 visible on the screen, portraying the participant and the opponent, providing the participant with  
150 the relative distance to the opponent. At the start of each trial, participants were provided with  
151 the goal to complete the trial in the fastest possible time and to give maximal effort; whether or  
152 not they beat the opponent was not important. When an opponent was present, participants were

153 told the opponent was of a similar performance level as the participants. Participants received  
154 no numerical feedback on heart rate, power, velocity, time passed, the distance covered,  
155 distance left or relative distance to the opponent.

156 Participants were free to change the gear throughout the time trial. Power output,  
157 velocity, distance, and gearing were monitored during the trial (sample frequency = 25Hz). Rate  
158 of perceived exertion (RPE) on a Borg-scale of 6-20 was asked after warming-up, before the  
159 start of the trial and at 500m, 1000m, 1500m, as well as directly after passing the finish line.  
160 The participants were told the RPE collection points were random throughout the trial.

161 All time trials were performed on the same day of the week, with a maximum of six  
162 weeks for all the visits. Participants were asked to keep changes in activity and sleep patterns  
163 to a minimum during the testing period. Furthermore, participants were asked to abstain from  
164 intense physical exercise for 24 hours as well as the consumption of solid food for two hours  
165 and caffeine for four hours, before visits. All trials were conducted in ambient temperatures  
166 between 18-21°C.

167

## 168 **Data analysis**

169 To investigate the effect of the experience gained over successive trials, the outcome variables  
170 of the four consecutive visits (visit 1, visit 2, visit 3 and visit 4) were compared. In order to  
171 analyse the influence of the two different opponents, the three different conditions (No  
172 Opponent, OP-SLOWFAST and OP-FASTSLOW) were compared.

173 Performance was analysed through two outcome variables: finish time and mean power  
174 output of the trial. The performance variables and the answers to the questionnaire on  
175 motivation, expected performance and expected finishing time, were analysed by a one-way  
176 repeated measurement ANOVA to reveal a difference between the visits or conditions ( $p < 0.05$ ).  
177 A post hoc analysis in the form of paired t-test, including Bonferroni correction, were performed

178 if a significant effect ( $p < 0.05$ ) was found. In order to study the ability to anticipate the future  
179 workload before exercise, a paired t-test was used to analyse the difference between expected  
180 and actual finishing time for each individual visit.

181 Pacing behaviour of the participants was investigated by analysing the time needed to  
182 cover each 250m segment of the 2-km trial. Assessing pacing behaviour through analyses of  
183 split times during the course of a trial is a commonly used method in literature (Konings et al.,  
184 2016; Lambrick et al., 2013). A two-way repeated measurement analyses ( $p < 0.05$ ) was used to  
185 investigate a difference in pacing behaviour between the different visits (segments \* visits) and  
186 between the different conditions (segments \* conditions). If a significant interaction effect  
187 ( $p < 0.05$ ) was found, indicating a difference in pacing behaviour, a post hoc analysis in the form  
188 of paired t-test, including Bonferroni correction, would be performed.

189 The RPE throughout the trial was analysed using a two-way repeated measurement  
190 analysis ( $p < 0.05$ ) to study difference in RPE during the different visits (segments \* visits) and  
191 the difference in RPE between conditions (segments \* conditions). A significant interaction  
192 effect would indicate a difference the RPE score over the segments for either the visits or the  
193 conditions, and would be instigate a paired t-test post hoc analyses, including Bonferroni  
194 correction.

195 In anticipation of all previously mentioned repeated measurement ANOVA analyses the  
196 sphericity was tested using Mauchly's test. If sphericity could not be assumed a Greenhouse-  
197 Geisser correction was used.

198

199

## Results

### 200 Development over successive trials

201 Mean (SD) of the questionnaires on motivation, expected performance and expected finishing  
202 time as well as the actual finish time and mean power output of each visit can be found in Table

203 1. During the course of the visits, there was no significant difference in the answers to the  
 204 questions concerning motivation ( $F_{3,27} = 1.09$ ,  $p = 0.370$ ,  $\eta^2_p = 0.108$ ), expected performance  
 205 ( $F_{3,27} = 0.558$ ,  $p = 0.628$ ,  $\eta^2_p = 0.061$ ) or expected finish time ( $F_{1.07, 9.61} = 2.812$ ,  $p = 0.125$ ,  $\eta^2_p$   
 206  $= 0.238$ ). However, a significant difference between expected and actual finishing time was  
 207 found during visit 1 ( $t = 2.808$ ,  $p = 0.020$ ,  $d = 0.888$ ), but not during visit 2, 3 and 4 ( $t = 1.686$ ,  
 208  $p = 0.126$ ,  $d = 0.533$ ;  $t = 1.987$ ,  $p = 0.078$ ,  $d = 0.628$ ;  $t = 1.893$ ,  $p = 0.094$ ,  $d = 0.599$ ;  
 209 respectively). A significant difference in both performance variables, finish time and mean  
 210 power output, was found ( $F_{3,27} = 9.972$ ,  $p < 0.001$ ,  $\eta^2_p = 0.526$  and  $F_{3,27} = 5.651$ ,  $p = 0.004$ ,  $\eta^2_p$   
 211  $= 0.386$ , respectively). The post hoc analyses revealed the finishing times of visits 2, 3 and 4  
 212 were significantly lower compared to visit 1 ( $t = 21.354$ ,  $d = 1.464$ ,  $p = 0.001$ ;  $t = 14.063$ ,  $d =$   
 213  $1.186$ ,  $p = 0.005$ ,  $d =$ ;  $t = 13.032$ ,  $p = 0.006$ ,  $d = 1.144$ ; respectively). Additionally, the mean  
 214 power output was significantly higher in visits 2, 3 and 4 compared to visit 1 ( $t = 11.847$ ,  $p =$   
 215  $0.007$ ,  $d = 1.094$ ;  $t = 9.784$ ,  $p = 0.012$ ,  $d = 0.987$ ;  $t = 7.301$ ,  $p = 0.024$ ,  $d = 0.856$ ; respectively).  
 216

217 \*\*\* Please insert Table 1 near here\*\*\*

218

219 The mean (SD) split times of the 250m segments of the trial for each visit are shown in  
 220 Figure 1. There was a significant difference between the individual 250m segments ( $F_{1.268, 11.414}$   
 221  $= 21.574$ ,  $p < 0.001$ ,  $\eta^2_p = 0.706$ ), and between the average values of the different visits ( $F_{3, 27}$   
 222  $= 9.972$ ,  $p < 0.001$ ,  $\eta^2_p = 0.526$ ). No significant interaction effect, indicating a difference in  
 223 pacing behaviour between the different visits, was found ( $F_{2.99, 26.91} = 1.665$ ,  $p = 0.198$ ,  $\eta^2_p =$   
 224  $0.156$ ).

225

226 \*\*\* Please insert Figure 1 near here\*\*\*

227

228 The mean (SD) RPE scores can be found in Figure 2. The RPE score was significantly  
229 different between the different segments ( $F_{1.66, 14.937} = 159.032$ ,  $p < 0.001$ ,  $\eta^2_p = 0.946$ ). The  
230 average RPE score was not significantly different between different visits ( $F_{3, 27} = 0.847$ ,  $p =$   
231  $0.480$ ,  $\eta^2_p = 0.086$ ). A significant interaction effect was found, indicating a difference in RPE  
232 score over the segments between the visits ( $F_{3.30, 29.74} = 3.245$ ,  $p = 0.032$ ,  $\eta^2_p = 0.265$ ). The post  
233 hoc analysis revealed that the RPE score at the 500m mark was significantly higher during visit  
234 1 compared to visit 3 ( $t = 7.568$ ,  $p = 0.022$ ,  $d = 0.870$ ) and visit 4 ( $t = 18.688$ ,  $p = 0.002$ ,  $d =$   
235  $1.367$ ). Moreover, the RPE score at the 500m was higher during visit 2 compared to visit 4 ( $t =$   
236  $17.047$ ,  $p = 0.003$ ,  $d = 1.303$ ). No significant differences in RPE between the visits were found  
237 at the start, 1000m, 1500m and finish.

238

239 \*\*\* Please insert Figure 2 near here\*\*\*

240

### 241 **Influence of opponents**

242 The difference in finishing time between the opponents calculated from the FAM and the  
243 constructed opponents which participants faced was:  $0.33 \pm 0.07$ s. The mean (SD) finishing  
244 times of the constructed opponents were OP-SLOWFAST:  $235.39 \pm 25.44$ s and OP-  
245 FASTSLOW:  $235.35 \pm 25.58$ s.

246 Between the conditions, there was no significant difference in the scores on motivation  
247 ( $F_{1.784, 16.057} = 0.783$ ,  $p = 0.460$ ,  $\eta^2_p = 0.080$ ), expected performance ( $F_{1.857, 16.711} = 0.545$ ,  $p =$   
248  $0.577$ ,  $\eta^2_p = 0.057$ ) or expected finish time ( $F_{1.567, 14.101} = 0.802$ ,  $p = 0.440$ ,  $\eta^2_p = 0.082$ ) (Table  
249 1). Additionally, no significant difference in finish time or mean power output were found  
250 between the trials with different conditions ( $F_{1.883, 16.48} = 0.612$ ,  $p = 0.544$ ,  $\eta^2_p = 0.064$  and  
251  $F_{1.720, 15.484} = 0.174$ ,  $p = 0.811$ ,  $\eta^2_p = 0.019$ , respectively) (Table 1).

252 The mean (SD) split times of each 250m segment of the trial under different conditions  
253 are shown in Figure 3. A significant difference in split time over the different segments was  
254 found ( $F_{1.378, 12.398} = 23.854$ ,  $p < 0.001$ ,  $\eta^2_p = 0.726$ ). No significant difference between the  
255 average split time between conditions ( $F_{2, 18} = 0.612$ ,  $p = 0.553$ ,  $\eta^2_p = 0.064$ ) or interaction  
256 effect, indicating a difference in pacing behaviour ( $F_{3.606, 32.457} = 0.1676$ ,  $p = 0.184$ ,  $\eta^2_p = 0.157$ ),  
257 were found. As no significant interaction effect was found, no post hoc analyses was performed.

258

259 \*\*\* Please insert Figure 3 near here\*\*\*

260

261 Mean (SD) scores for RPE can be found in Figure 4. The RPE score of the individual  
262 segments was significantly different ( $F_{4, 36} = 144.757$ ,  $p < 0.001$ ,  $\eta^2_p = 0.941$ ). Additionally, the  
263 average RPE score of the distinct conditions was significantly different ( $F_{1.627, 14.643} = 4.918$ ,  $p$   
264  $= 0.029$ ,  $\eta^2_p = 0.031$ ). No significant difference in RPE score over the segments between the  
265 different conditions was found ( $F_{2.131, 19.182} = 0.292$ ,  $p = 0.767$ ,  $\eta^2_p = 0.031$ ), therefore, no post  
266 hoc analyses was performed.

270

## Discussion

271 This study is the first to examine characteristics of pacing behaviour of novice youth exercisers  
272 in response to exercise in a controlled laboratory setting. The findings identify that the velocity  
273 distribution of the novice youth decrease in velocity between the 250m and 750m mark, and  
274 display an increase in velocity at the 1750m to 2000m segment. This is a more complex pacing  
275 behaviour than seen previously in young children (~5-8 years) (Micklewright et al., 2012) and  
276 the observed overall U-shaped velocity distribution, is generally associated with the goal-

277 directed preservation of energy to successfully execute an exercise task. This suggests increased  
278 sophistication of pacing is evident in youths compared to young children, while it is also  
279 interesting that during the first visit, a significant difference was found between the amount of  
280 time participants thought was needed to finish the trial and the actual completion time of the  
281 trial. The variety in expected finishing time among the cohort during the first visit was also  
282 substantially larger (SD of visit 1: 249.18s) compared to other visits (average SD visits 2-4:  
283 134.74s) . Both findings attest to the novelty of the activity for the participants before the first  
284 visit and the potential impact of acquired experience. The finding that the pacing behaviour of  
285 youth exhibits characteristics associated the goal-directed reservation of energy during the  
286 execution of a novel exercise task, supports the notion that an inherit pacing template is present  
287 from a young age (Foster et al., 2009; Lambrick et al., 2013).

288

289 The secondary aim of this research was to investigate the influence of the experience gained  
290 over successive trials on pacing behaviour and performance. However, no change in pacing  
291 behaviour was found throughout the visits. Nevertheless, the 8.1% increase in power output and  
292 5.1% decrease in finishing time during the second visit indicate an improvement in performance  
293 after gaining experience during the first visit. The observation that there was no significant  
294 increase in performance during visits two, three and four suggests that a single familiarization  
295 trial was sufficient to heighten the performance in novice youth. A similar conclusion was  
296 reached in a research in children (aged 9-11 years) performing a running task with a similar  
297 duration to the task in the current study (Lambrick et al., 2013). This study found a 2.6-3.1%  
298 decrease of finishing time during the second visit and no significant further decrease during a  
299 third visit. Moreover, the study did not find significant difference in pacing behaviour between  
300 the three visits. These results strengthen the notion that novice performers can increase  
301 performance after gaining experience in only a single trial.

302           It has previously been proposed that the anticipation of workload, and the adjustment of  
303 workload anticipation during exercise, form part of the underlying mechanism of the regulation  
304 of energy (Edwards & McCormick, 2018; Hettinga et al., 2009; Reid et al., 2017). In the current  
305 study, the ability to anticipate the workload of the exercise was measured by analysing the  
306 difference between the expected finish time and the actual finishing time of each visit. By  
307 comparing the first and second visit, the gap between the expected finish time and the actual  
308 finishing time decreased by 66.2%, suggesting greater awareness of performance capabilities  
309 as experience grew. It should be noted that the condition of visit two differed between  
310 participants, as result of the randomisation of conditions between visits two, three and four.  
311 However, there was no significant difference in expected or actual finishing time between the  
312 conditions, indicating that the increase in awareness of performance capabilities was not  
313 influenced by the condition of the second visit. Moreover, in the first visit, the expected and  
314 actual finishing time were significantly different. Contrary to this, there was no significant  
315 difference between expected and actual finishing time during the other visits. These findings  
316 point to an improved ability to anticipate the workload of the exercise as a whole in addition to  
317 greater confidence in the performance capability. The increase in the skill to anticipate the total  
318 workload might be the underlying mechanism of the increase in performance after the first visit.

319           In literature, RPE has been proposed as a mediating factor in the regulation of energy  
320 distribution by the cognitive anticipatory skill (Tucker & Noakes, 2009). The results of the  
321 current study present a decrease in RPE score at the 500m mark between visit one and visit  
322 three and four, as well as between visit two and four. A decrease in RPE during the initial phase  
323 of the race may well indicate that the participants were actively changing their anticipation of  
324 the future workload during the exercise (Faulkner, Parfitt, & Eston, 2008). Therefore, it could  
325 be suggested that the skill to anticipate the future workload during exercise takes more than one  
326 visit worth of experience to be adapted. This slower change in anticipatory ability could be the

327 underlying mechanism which enabled a change in pacing behaviour over a longer period of  
328 time, as seen in previous studies (Menting et al., 2019; Wiersma et al., 2017). Future research,  
329 preferably longitudinal, should be performed to gain more insight into the development of  
330 pacing behaviour in relation to anticipatory skill.

331

### 332 **Influence of opponents**

333 No difference in performance or pacing behaviour was found between the different conditions  
334 in the youth athletes in the current study. In contrast, previous studies found a decreased  
335 performance in novice children (9-11 years old) facing opponents (Lambrick et al., 2013) and  
336 an increase in performance in novice 19 years olds facing opponents (Corbett, Barwood,  
337 Ouzounoglou, Thelwell, & Dicks, 2012). Previous literature states the adaptation of the skill to  
338 pace in the presence of opponents is not yet fully developed in youth athletes (Menting et al.,  
339 2019), and therefore novice youth might not yet be able to use the presence of opponents to  
340 increase their performance, as seen in adults who have been found to perform better when  
341 opponents are present (Konings et al., 2018; Konings et al., 2016; Williams et al., 2015). It  
342 could be that the attentional needs of youth exercisers in the adolescence development phase  
343 are more aimed at properly pacing an exercise bout and internally developing their self-paced  
344 behaviour and that they therefore consider opponents to a lesser extent, and for the very young  
345 it might therefore be detrimental to performance. The current group of novice youth exercisers  
346 (15.8±1.0 years old) were in an age range in between the two previous studies in 9-11 year olds  
347 (Lambrick et al, 2013) and 19 year olds (Corbett et al, 2012). It is therefore possible that for  
348 youth exercisers in this specific age range, an increase in performance through the gathering of  
349 experience as discussed previously seems more important for performance improvements,  
350 while the presence of opponents seems of a lesser importance.

351 Furthermore, previous research pointed to notion that the instructions regarding the  
352 presented opponents as well as the behaviour of the opponents, could determine the impact on  
353 participant performance (Konings, Schoenmakers, et al., 2016; Williams et al., 2015). In the  
354 current study, the participants had the goal of finishing the 2km trial as fast as possible,  
355 regardless of beating the opponent. It seems plausible that the lack of influence of the opponent  
356 could be caused by a lack of engagement with the opponent. It should also be acknowledged  
357 that the participants in the current study were active in a variety of both individual and team  
358 sports. Previous research has pointed out that sport background influences goal-orientation of  
359 an athlete, and therefore, impacts the behaviour of athletes to the presence of opponents during  
360 exercise performance (van de Pol & Kavussanu, 2012). It would therefore be interesting for  
361 future studies to investigate the effect of different exercise backgrounds, goal-orientations and  
362 instruction regarding opponents, on performance and pacing behaviour in youth.

363

364

### **Conclusion**

365 The pacing behaviour of novice youth exercisers exhibits characterisations which are associated  
366 with goal-directed reservation of energy during novel exercise, attesting to the existence of a  
367 pacing template in this population. The experience gained during a single trial seems sufficient  
368 to cause an improvement in performance, but not a change in underlying pacing behaviour. The  
369 large increase in performance after only one visit is theorized to be caused by an improved  
370 ability to accurately anticipate the workload of the exercise as a whole. The ability to anticipate  
371 future workload during exercise, and regulate the energy distribution accordingly, might be  
372 among the underlying mechanisms of the long term changes in pacing behaviour that occur  
373 throughout adolescence. The lack of influence from the presence of opponents could be  
374 appointed to the development phase of the youth exercisers, in which they are more focusing  
375 on developing the self-regulated pacing of a bout of exercise and to a lesser extent on the

376 presence of opponents. As the current study is the first to analyse the performance and pacing  
377 behaviour of novice youth exercisers in a controlled environment, future research should be  
378 conducted to further investigate the factors underlying the development of pacing behaviour  
379 and performance in this age group. A suggested starting point for this research is to further  
380 explore the influence of self-regulatory skills and anticipation of workload on the development  
381 of pacing behaviour and performance.

382

383

### **What does this article add?**

384 The skill to distribute energy over an exercise task is important in both the optimisation of  
385 exercise performance and the safeguarding the well-being of exercisers by evading burn-out,  
386 dropout and overtraining. Adolescence is an important phase in the development of the pacing  
387 skillset. However, there is only a small sum of literature which evaluates the development of  
388 performance and pacing behaviour during adolescence. Even less is known on the underlying  
389 mechanisms of the development of pacing behaviour and performance during adolescence. The  
390 current study made a first step in uncovering these mechanisms by investigating possible  
391 underlying factors of pacing behaviour and performance development of youth exercisers in a  
392 controlled laboratory setting. This study confirmed the existence of a pacing template in novel  
393 youth and emphasizes importance of the gathering of experience with an exercise task for  
394 performance development. Additionally, it is suggested that the ability to anticipate workload  
395 before and during exercise influences pacing behaviour development both in the short and long  
396 term. The lack of behavioural change after introduction of opponents in this stage in the  
397 development process, introduces to the idea that novice youth are primarily engaged with  
398 properly pacing their exercise bout and are less concerned with the behaviour of opponents.
