1 **Supplementary Information 1: Hazard area performance with optimised, global and hold-** 2 **back parameters**

3 At each of the six study sites we optimise the two parameters in the SHALRUN-EQ model required
4 to predict hazard area, initiation angle (θ_m) and stopping angle (θ_s), by sampling values for each
5 parameter uniformly in 1 degree increments over the range [20,70] for initiation angle and [0,50] for
6 stopping angle, and imposing the requirement: $\theta_m > \theta_s$. For our objective function, we use the area
7 under the receiver operating characteristic (ROC) curve, comparing landslide hazard derived from
8 hazard area to the inventory of observed landslides at each site. The optimisation surfaces are
9 shown in Figure S1. To generalise our results, we then take arithmetic means of the optimum
10 initiation and stopping angles, to generate hazard area predictions using a single 'global' rule
11 averaged over all six inventories (Table S1). To remove the influence of test data on the test itself,
12 we re-run the hazard area prediction for each inventory as a hold back-test, in which we re-calculate
13 the initiation and stopping parameters excluding the optimised values from that inventory and using
14 only the remaining five inventories.

15 We find that the differences in ROC curves (Figure S2) and area under the curve values (Table S1)
16 are fairly subtle. Hazard area with global average parameters performs well overall, with AUC values
17 that range from 0.78 to 0.86. Hazard area with parameters that are optimised for each inventory
18 offers only a slight further improvement, with AUC increased by <3% in each case (Table S1).
19 Optimised initiation and stopping angles can differ quite radically between sites, ranging from 31-45°
20 for initiation angle and from 3-19° for stopping angle. This might signal cause for concern about how
21 feasible it is to find a single general rule, given such variability in optimum parameters between sites.
22 However, hazard area skill is relatively insensitive to parameter variation close to the optimum
23 parameters, as indicated by the relatively smooth and gentle peaks of the optimisation surfaces in
24 Figure S1. Thus, the (sometimes large) differences between global and optimised parameter values
25 do not translate into large performance differences between hazard area predictions using global or
26 optimised parameters. The use of hold-back rather than global parameters results in an even smaller
27 difference in performance; AUC values are reduced by <1% for every inventory and hazard area is
28 still the best metric at all sites. For this reason, we include hold-back tests here but report results
29 from global average parameters rather than hold-back parameters in the paper for simplicity. It is

30 these global average parameters (initiation angle of 40° and stopping angle of 10° when rounded to
 31 one significant figure) that form the basis of our simple rule, and that we would recommend when
 32 applying the SHALRUN-EQ approach to a new location (in the absence of a landslide inventory with
 33 which to test and calibrate the parameters).

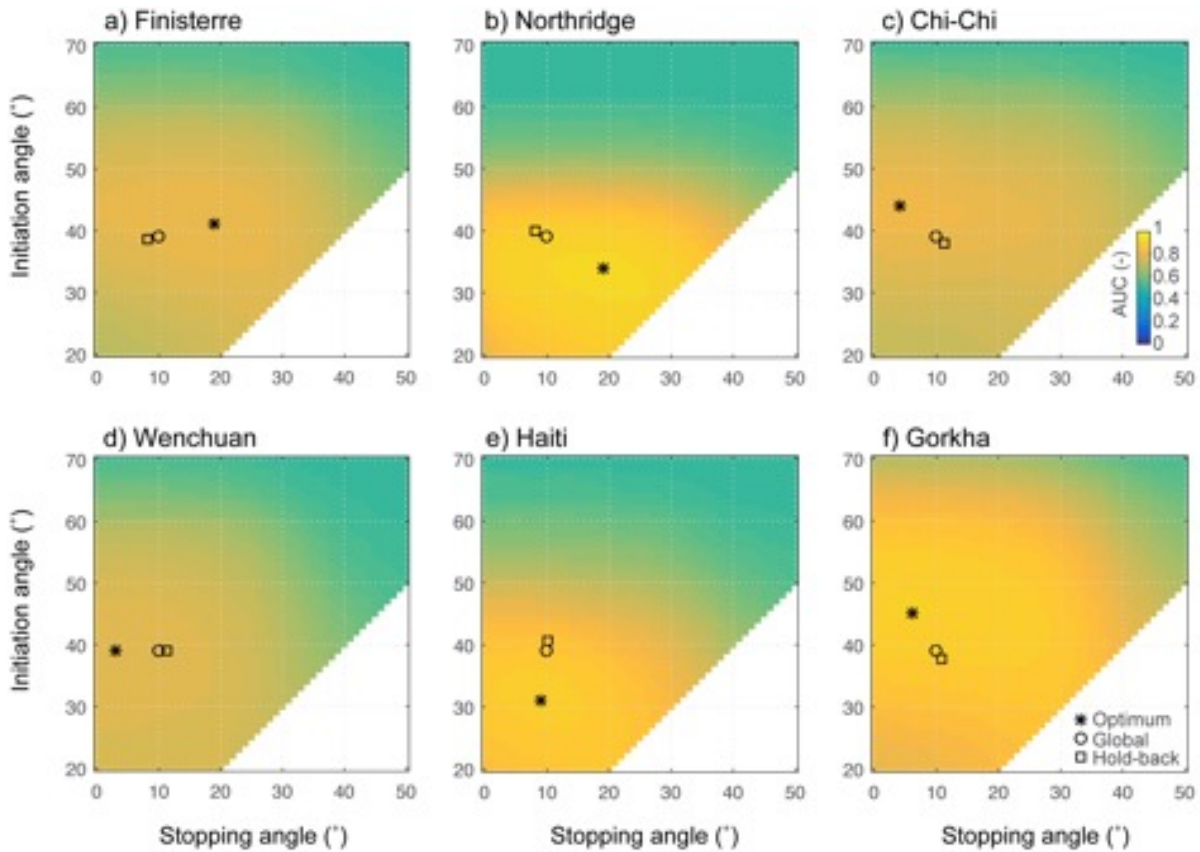

34

35 Table S1: Parameter values and areas under the ROC curve for the six inventories

	Parameters		Area Under ROC Curve		
	Initiation slope θ_i (°)	Stopping slope θ_s (°)	Hazard area optimised	Hazard area global	Hazard area holdback
Finisterre	34	19	0.91	0.89	0.88
Northridge	41	19	0.80	0.79	0.78
Chichi	44	4	0.80	0.80	0.79
Wenchuan	39	3	0.78	0.78	0.78
Haiti	31	9	0.88	0.86	0.85
Gorkha	45	6	0.89	0.88	0.88
Average	39	10	0.84	0.83	0.83
1 σ	6	7	0.1	0.1	0.1

36

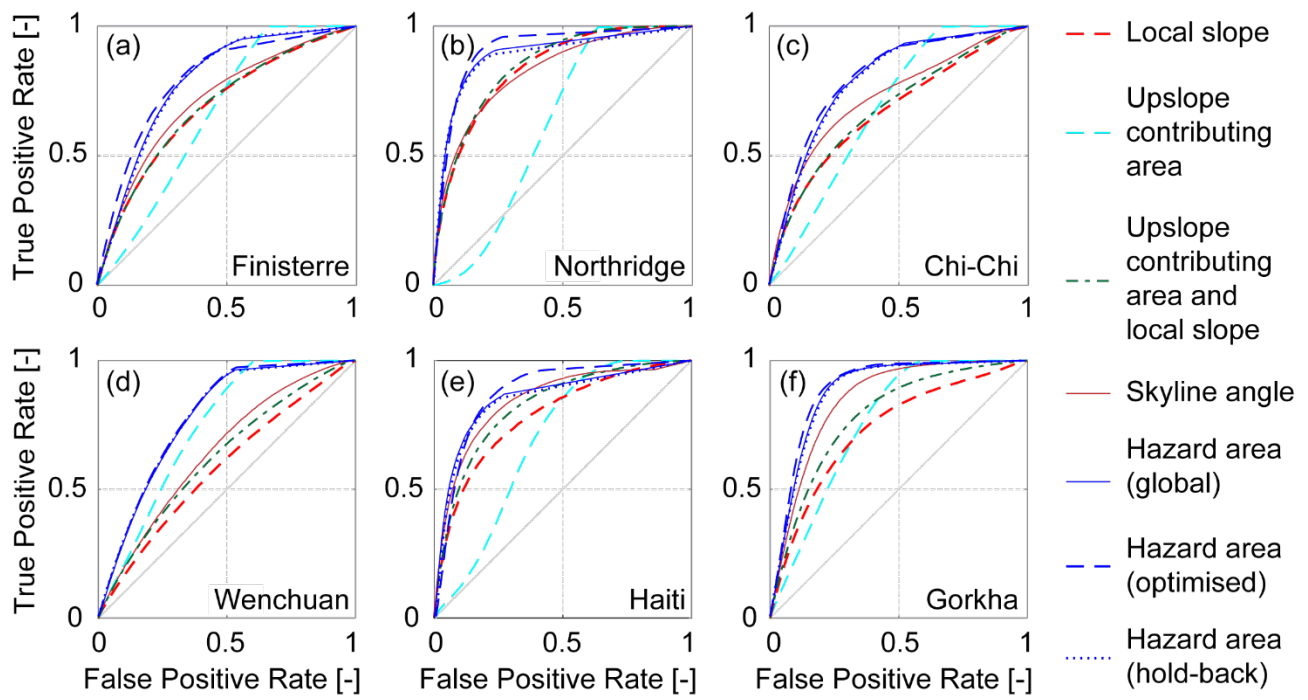

37

39

40 Figure S1: Model predictive skill for SHALRUN-EQ for each of the six landslide inventories across
 41 reasonable ranges for the two parameters, initiation angle (θ_m) and stopping angle (θ_s). Predictive
 42 skill is quantified using area under the receiver operating characteristic curve. The six inventories
 43 are: a) Finisterre, b) Northridge, c) Chi-Chi, d) Wenchuan, e) Haiti, f) Gorkha. Symbols show the
 44 parameter combinations from site specific optimisation, global average, and hold-back average.

45

46

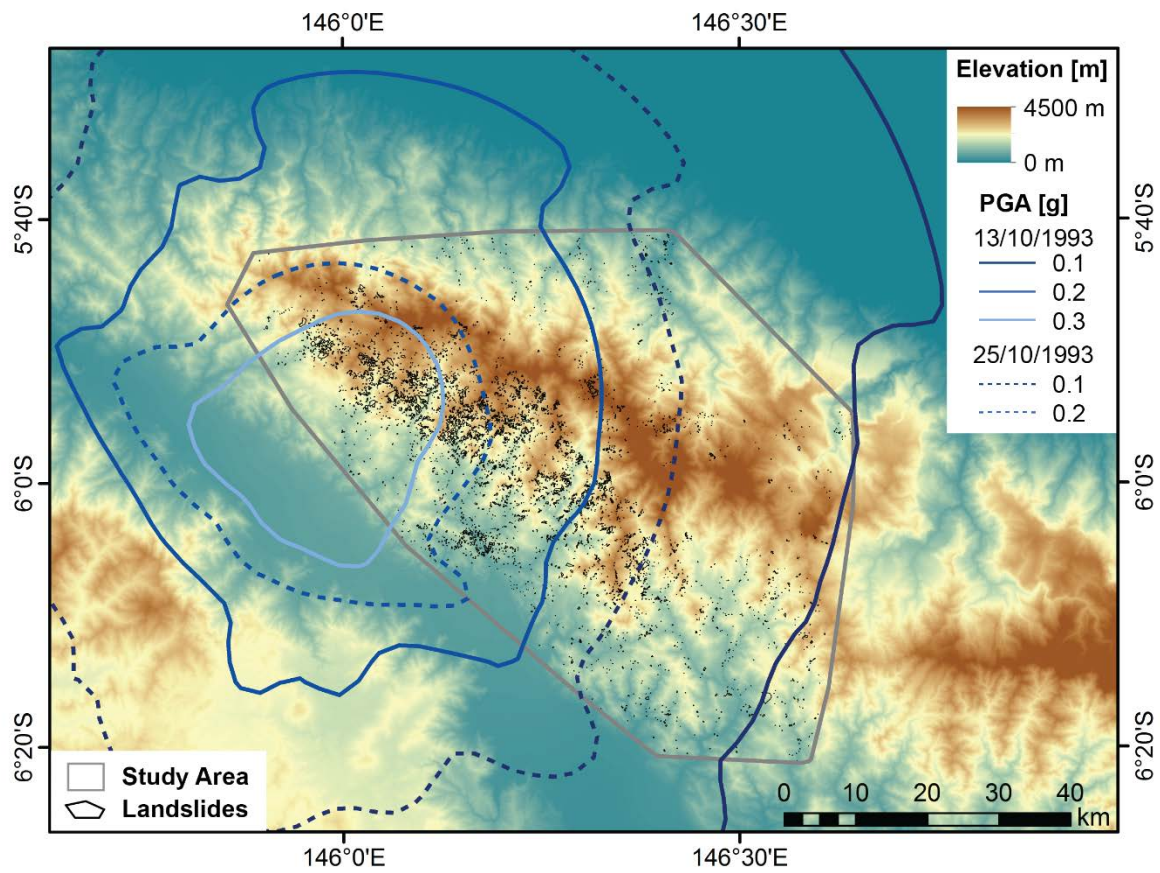

47 **Figure S2:** Receiver operating characteristic (ROC) curves for the six landslide inventories and five
 48 metrics examined here, as shown in Figure 6 of the paper, but with the addition of ROC curves for
 49 hazard area with (1) site-specific optimised parameters and (2) hold-back parameters (i.e., global
 50 averages from five sites excluding the test site). The six inventories are: a) Finisterre, b)
 51 Northridge, c) Chi-Chi, d) Wenchuan, e) Haiti, f) Gorkha. False positive rate is given by the number
 52 of false positives divided by the sum of false positives and true negatives. True positive rate is
 53 given by the number of true positives divided by the sum of true positives and false negatives. The
 54 1:1 line represents the naïve (random) case. Curves plotting closer to the top left corner of each
 55 panel represent better model performance.

56

57 **Supplementary Information 2: Table S2. Study site characteristics**

	Northridge	Finisterre	Chi-Chi	Wenchuan	Haiti	Gorkha
Geology	Weakly cemented sedimentary rocks ^[1] .	Volcaniclastic & volcanic rocks thrust over coarse-grained foreland deposits capped by limestones ^[9]	Neogene sediments and older metasedimentary rocks ^[15]	Granitic massifs, a passive margin sequence, and a thick foreland basin succession ^[22]	Sub-parallel belts of igneous, metamorphic and sedimentary rocks ^[28]	Variably metamorphosed sedimentary and igneous rocks, some sedimentary metasedimentary ^[33]

92 **combination**

93

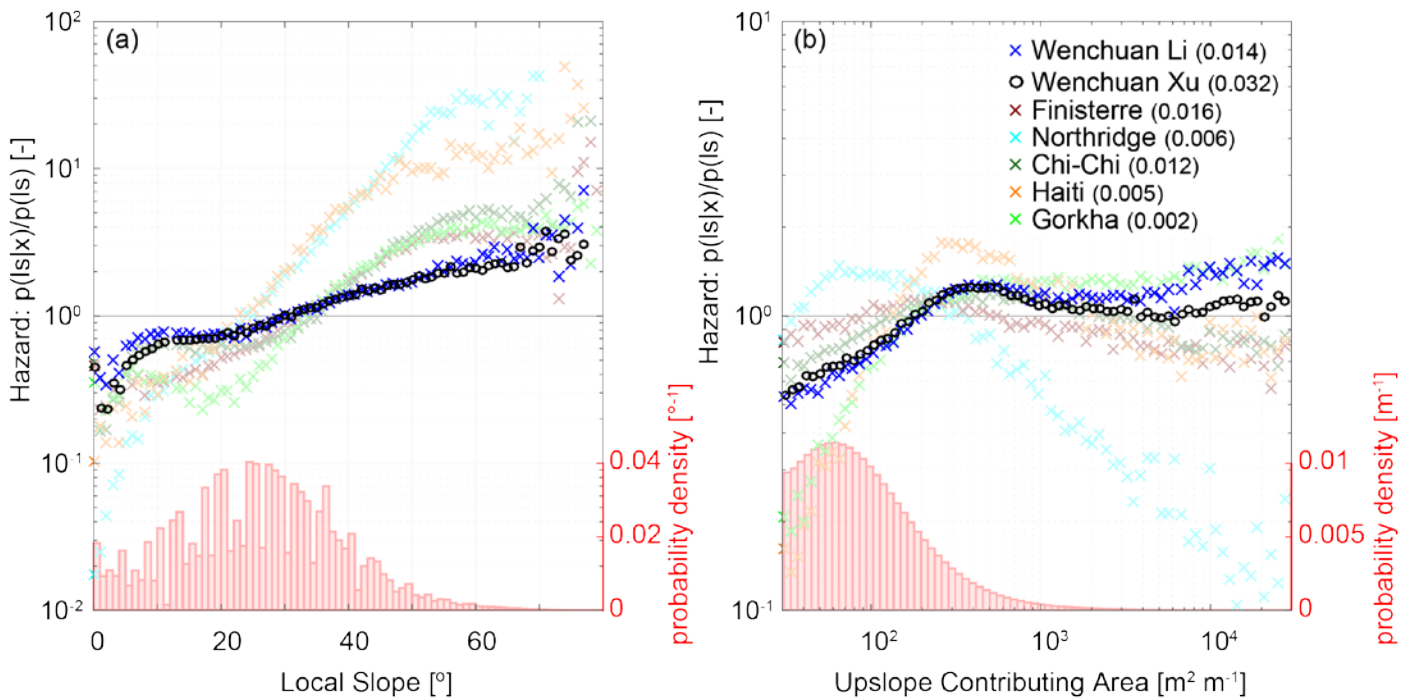

94

95 **Figure S9.** Two-dimensional plots of landslide hazard, defined as conditional landslide probability
96 $P(L|s,a)$ normalised by study area average landslide probability $P(L)$, where s is local slope
97 normalised by the study area average slope and a is upslope contributing area normalised by the
98 upslope contributing area at which channels begin. Grey cells indicate slope-area pairs with data
99 but with no cells touching a landslide. Fainter colours indicate landslide hazard estimates that do
100 not differ significantly from the study area average.

101

102

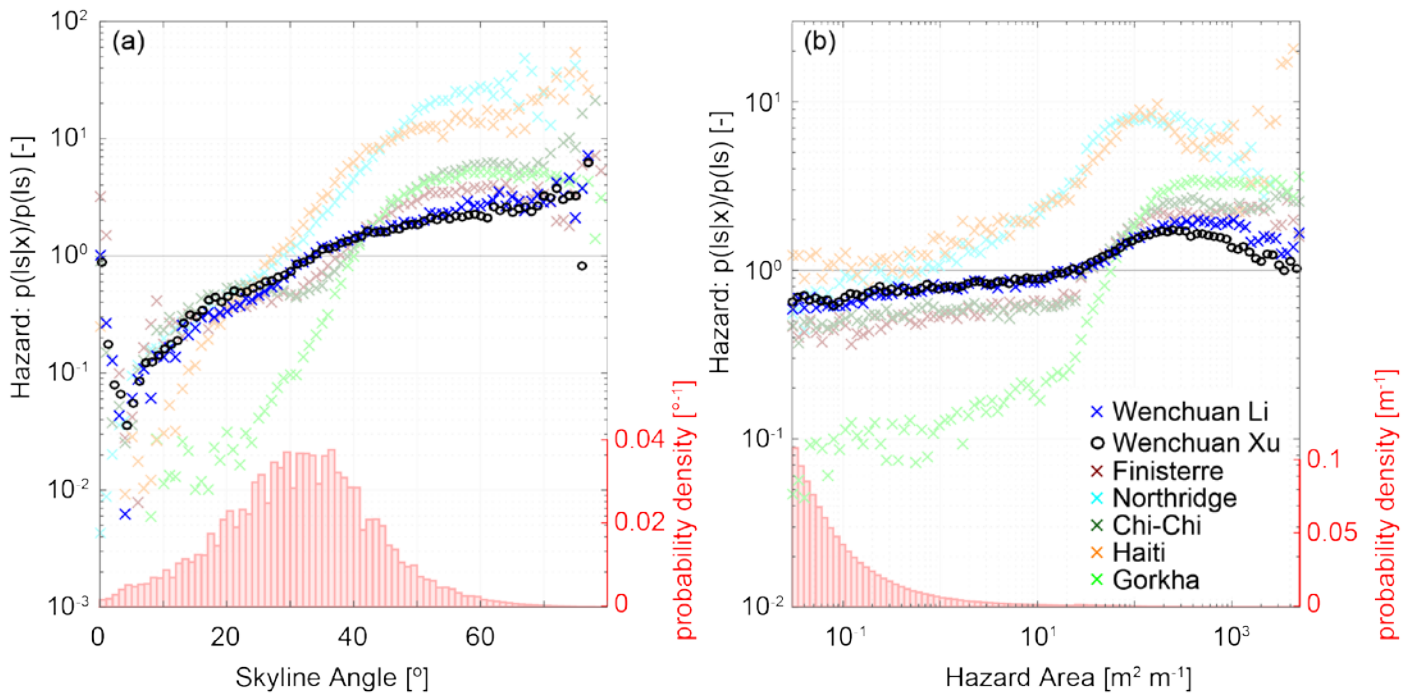

103 **Supplementary Information 4: Impact of landslide inventory uncertainty and DEM resolution**

104

105 **Figure S10.** Comparing the impact of different landslide inventories. Landslide hazard is defined
106 as $P(L|x) / P(L)$ and is estimated from two different landslide inventories for the Wenchuan
107 earthquake, where x is a) local slope, and b) upslope contributing area per unit contour length.
108 Numbers in brackets show study area average landslide probabilities. Results from other
109 earthquakes are shown in faint colours for context. The results from Li et al. (2014) and Xu et al.
110 (2014) for the Wenchuan earthquake are strongly similar.

111

112

113 **Figure S11.** Comparing the impact of different landslide inventories. Landslide hazard is defined
 114 as $P(L|x) / P(L)$ and is estimated from two different landslide inventories for the Wenchuan
 115 earthquake, where x is a) skyline angle and b) upslope contributing area per unit contour length.
 116 Red bars show histograms of skyline angle and hazard area over the six inventories. Results from
 117 other earthquakes are shown in faint colours for context. The results from Li et al. (2014) and Xu et
 118 al. (2014) for the Wenchuan earthquake are strongly similar.

119 **Table S3.** Area under the ROC curve for the five hazard metrics over the six coseismic landslide
 120 inventories. The best performing metric for each inventory is in bold, the second best is in italics.

	Hazard area	Skyline angle	Slope + upslope contributing area	Local slope	Upslope contributing area
Northridge 10	0.91	0.91	0.86	0.85	0.63
Northridge 20	0.91	<i>0.88</i>	0.86	0.85	0.63
Northridge 30 (NED DEM)	0.89	0.83	<i>0.84</i>	<i>0.84</i>	0.62
Northridge 30 (SRTM DEM)	0.66	0.83	0.83	0.83	0.64
