**Enhanced model of the innovation-decision process, for
modular-technological-process innovations in construction.**

Journal:	<i>Construction Innovation: Information, Process, Management</i>
Manuscript ID	CI-02-2021-0021.R2
Manuscript Type:	Research Article
Keywords:	4D BIM, Construction Scheduling, Diffusion, Innovation, Planning & Management, BIM

Enhanced model of the innovation-decision process, for modular-technological-process innovations in construction.

Purpose: An enhanced model of the innovation-decision process, specifically for construction is established. As context, innovation diffusion theory (IDT) is concerned with explaining how some innovations successfully stick whilst others fail to propagate. Because theoretical models provide abstracted representations of systems/phenomena, established IDT models can help decision-making units (DMUs) with innovation-related sense-making and problem solving. However, these occasionally fail, or require enhancement to represent phenomena more successfully. This is apparent whenever middle-range theory seems ill-fitted to the complexity of construction.

Design/methodology/approach: Qualitative research via 13 semi-structured interviews occurred, with participants recruited via convenience and purposive sampling strategies. The work forms part of a broader mixed-method study informed by a research philosophy of pragmatism, investigating the applicability of classic IDT to the adoption of 4D Building Information Modelling (4D BIM) by the UK construction sector.

Findings: This diffusion study resulted in the adaptation of an existing innovation-decision process model, ensuring a better contextual fit. Classified more specifically as a modular-technological-process innovation, 4D BIM with its potential to provide construction planning improvements is used as a vehicle to show why, for construction, an existing model required theoretical extensions involving additional stages, decision-action points, and outcomes.

Originality: An enhanced model of the innovation-decision process, specifically for construction, is established. This construction-centric contribution to innovation diffusion theory, will be of interest to construction scholars, and to practitioners.

Implications: This model can assist construction industry actors with future adoption/rejection decisions around modular-technological-process innovations. It also aids understanding of scholars and researchers, through its various enhancements, and

1 • by reinforcing the importance of existing diffusion concepts of compatibility and
2 trialability, for these innovation types.

1 Introduction

In attempting to improve aspects of construction project-delivery, efforts sometime focus on how to exploit relevant innovations, harnessing their benefits as possible solutions to key challenges. An innovation is some 'thing', unfamiliar to an entity, that can facilitate product, process, or systemic improvements. In this work, the concern of time predictability in the delivery of UK construction projects is discussed, before 4D BIM is briefly introduced and positioned as an innovation with potential to provide improvements to construction planning and possibly to project time performance. However, there are concerns around the prospective industry absorption of 4D BIM because innovations do not always have their promised transformational effect, and they may 'take off' more slowly than expected, or not at all. Classic Innovation Diffusion Theory (IDT) helps explain how some innovations successfully stick, whereas others fail to do so. The phenomena of innovation diffusion occurs across society, but as the construction sector in particular, is perceived to suffer from a low 'innovation rate', this topic remains worthy of investigation within the context of construction.

The twin aims of this work are: to investigate the applicability of classic IDT to the adoption of 4D BIM by the UK construction industry, and; to use a study of 4D BIM diffusion to build upon classic IDT, developing a more relevant model for the construction sector for similar innovations. Following discussions around time predictability, innovation, classic innovation diffusion theory (IDT), and a demand for further research into construction innovation diffusion, 4D BIM is then defined as a modular-technological-process innovation. Then, synthesised results from a doctoral research programme focusing on the diffusion of 4D BIM are presented. These reveal how for the construction sector, an existing albeit too-general innovation-decision process model required theoretical extension to better serve industry actors in their diffusion considerations about modular-technological-process innovations.

Time predictability problem in construction project delivery

Construction is perceived as underperforming, particularly regarding project delivery (Love *et al.* 2011). Industry reviews regularly identify long-term concerns and there have been several calls to reform apparent poor performance. Recurring criticisms involve issues such as fragmentation, inefficiency and waste (Egan 1998, Wolstenholme 2009, Farmer 2016, McKinsey Global Institute 2017). Furthermore, the varying ability

of construction organisations to respond to, and capitalise on innovations have been highlighted (Larsen and Ballal 2005, Hosseini *et al.* 2015, Murphy *et al.* 2015). Reviewing long term inefficiency concerns, Egan (1998) highlights how innovative technologies and processes, including 3D object orientated modelling may provide solutions, stressing also the need for industry performance measurement. Following such recommendations, use of UK industry-standard Key Performance Indicators (KPI's) commenced in 1999. Particularly relevant here is the KPI 'time predictability', in which, Egan (1998) originally advised targeting a 10% annual reduction. Such focus on improving the time predictability of UK construction projects remains. The UK construction 'Vision for 2025' strategy document (HM Government 2013) calls for 50% faster project delivery by 2025, with reductions in overall time, from inception to completion, for new build and refurbished assets, benchmarked against 2013 UK industry performance¹. Despite such aspiration, analysis of annual KPI data reveals that UK construction project time predictability has not demonstrated sustained improvements in any measure of time predictability, and more than half of UK construction projects continue to exceed their agreed time schedules (entire project durations). Table 1 shows annual KPI data reported for measures of construction time predictability in the ten-year period 2009 to 2018, also providing the 10-year average.

Table 1: Construction time predictability for years 2009–2018, percentage of projects and phases delivered on time or better. Adapted from Glenigan (2018)

INSERT TABLE 1 HERE

4D BIM - potential solution

Crotty (2012) asserts how poor-quality project information results in two key issues for the UK construction industry, poor (time and cost) predictability and profitability. A UK government drive for all major construction projects to be working at “*fully collaborative 3D BIM (with all project and asset information, documentation and data being electronic) as a minimum by 2016*” was an important step toward improving the quality of project information across the industry (HM Government 2017). This was based on the belief that BIM is an innovation to improve design output quality, and

¹ 2013 benchmark where only 45% of UK construction projects were delivered on, or before their original planned project end dates.

1 overall design and construction processes including the time performance of
2
3 1 construction projects (Li *et al.* 2009, Sacks *et al.* 2018). BIM enables use of 4D
4 2
5 3 methods, where the dimension of time is linked to the 3D model ($x + y + z + t$) allowing
6 4
7 5 visualisation and aiding communication of the spatiotemporal relationships of
8 6
9 7 construction activities (Liston *et al.* 2001, Buchmann-Slorup and Andersson 2010).
10 8
11 9 Literature considers use of 4D methods as an aid to planning, and a useful addition to
12 10
13 11 project scheduling (Koo and Fischer 2000). 4D BIM can also be used to analyse
14 12
15 13 construction schedules to assess their implementation (Mahalingam *et al.* 2010, Trebbe
16 14
17 15 *et al.* 2015) thus helping reduce errors through plan interrogation and validation.
18 16
19 17

20 10
21 11 Given the emphasis on the need for quicker delivery of construction projects, the
22 12
23 13 continuing record of poor time predictability, and the broad endorsements that BIM
24 14
25 15 implementation can improve project delivery, there is presently much focus on how 4D
26 16
27 17 BIM can improve the planning of construction projects. However, whilst it appears that
28 18
29 19 4D BIM is a process-based innovation that can help improve construction project time
30 20
31 21 predictability, because concerns have previously been identified with innovation
32 22
33 23 adoption in construction (Winch 1998, Larsen and Ballal 2005) more research into
34 24
35 25 industry innovation diffusion efforts are encouraged (Larsen and Ballal 2005, Harty
36 26
37 27 2008).
38 28
39 29

40 20 ***Innovation***

41 21 An innovation is not the generation of an idea, but instead involves exploitation,
42 22
43 23 implementation and management of such ideas, or inventions, creating value through
44 24
45 25 their practical and commercial benefits (Kastelle and Steen 2011). Innovations offer
46 26
47 27 non-trivial improvements in products, processes or systems and are unfamiliar to the
48 28
49 29 company/institution (aka decision-making units) developing/making use of them
50 30
51 31 (Hosseini *et al.* 2015). Innovations should be considered in terms of their disruption to
52 32
53 33 the systems they are introduced into, with systems being considered as either simple,
54 34
55 35 complicated or complex. In construction, both projects (Baccarini 1996, Williams 1999)
56 36
57 37 and the industry itself (Bertelsen 2003, Harty 2005), have been described as complex
58 38
59 39 systems, meaning they have large numbers of parts, with uncontrollable dynamics,
60 40
making all possible outcomes difficult to predict (Loosemore 2014). Whilst construction
innovations could seemingly help bring about time and cost reductions, and safety and
quality improvements, thus improving competitive advantage and market share, when

1 compared against other sectors, very frequent innovation in construction does not
2 appear to occur. One explanation offered by Dubois and Gadde (2002) is that, because
3 of the complexity of construction, its system “*favours productivity in projects, while*
4 *innovation suffers*” (p629). Though a low industry innovation rate is refuted by Winch
5 (2003), such framing remains useful when discussing innovation diffusion in
6 construction.

7 *Construction innovation – types and frequency*

8 Slaughter (1998, 2000) advising also of the impacts that innovations can have on
9 systems, conceptualises five innovation-types in construction. These are: ‘incremental
10 innovations’ offering minor improvements over existing practices with minimal impacts
11 on a system; ‘architectural innovations’ whose consequences may mean reshaping many
12 system constituents; ‘modular innovations’ which may produce significant
13 improvements but may not require alterations of other system-level components;
14 ‘system innovation’ being the introduction and interaction of multiple complementary
15 innovations, and finally; ‘radical innovations’ completely new approaches, meaning a
16 redesign of the entire system being necessary. Slaughter advises that the implementation
17 of each type needs varying levels of managerial input/commitment. On this, researchers
18 (Koskela and Vrijhoef 2001, Reichstein *et al.* 2005) argue that the most frequent
19 innovations in construction are incremental or modular types, and are usually product-
20 rather than process- based, generated by suppliers, because of difficulties in
21 implementing more radical innovations requiring larger scale systematic changes.
22 Similar to Winch (2003), others (Taylor and Levitt 2004, Taylor *et al.* 2004) argue that
23 the rate of incremental product-based innovations in construction is no worse than in
24 comparable sectors, yet because of the structural complexity of project-based industries,
25 systemic process-based innovations that need to cross organisational boundaries diffuse
26 slower. And whilst Koskela and Vrijhoef (2001) call for the introduction of more
27 radical process-based innovations, Winch (1998) reflects that “*innovation efforts in the*
28 *industry are disproportionately orientated towards product-enhancement rather than*
29 *process-improvement*”.

30 *BIM and 4D BIM as innovations*

31 Despite this, the introduction of Building Information Modelling (BIM) within
32 construction, has been a very visible technological innovation and the Organisation for

Economic Cooperation and Development note how technological innovations can be categorised either as product or process innovations. Poirier *et al.* (2015), also agree that technological innovations include both [these types](#). Succar (2009), identifies the impact of BIM thus, “*Building Information Modelling (BIM) is an emerging technological and procedural shift within the Architecture, Engineering, Construction and Operations (AECO) industry*”. BIM has variously been classified both as an innovation (Davies and Harty 2013) and as disruptive technology (Succar *et al.* 2012). Poirier *et al.* (2015) note “*BIM is seen by many as being a disruptive innovation, which is bringing about the reconfiguration of practices in the AEC industry*”. Gledson (2016) concurs, identifying that “*the most prominent radical, transformative and disruptive innovation to hit construction industry is the use of Building Information Modelling*”.

Building upon these various definitions of BIM as a technological innovation, a more detailed classification of 4D BIM being a modular-technological-process innovation is proposed. This is because:

- As above, BIM is widely considered to be a ‘technological innovation’ (Succar 2009, Dainty *et al.* 2017, Li *et al.* 2017).
- Though (3D) BIM is considered as “*an integration of both product and process innovation*” (Georgiadou 2019), 4D BIM which enables a new way of planning, is more readily ‘process innovation’ because it facilitates improvements in the process of production. Also, the act of 4D planning in making use of BIM technology models only the construction process itself, rather than the building product (Elghaish and Abrishami 2020).
- 4D BIM also meets Slaughter’s (1998; 2000) conceptualisation of a ‘modular innovation’, as it allows better modelling of the planned construction process, which can result in substantial production improvements. The process involves using 4D technology either as a substitute for more conventional planning and scheduling tools, or as an ‘add-on’ to existing planning tools, meaning it does not require the alteration of other ‘system-level’ components.

For DMUs unfamiliar with BIM/4D BIM, these are innovations. They can provide process related benefits; generate value to organisational strategic outcomes; and enable competitive advantages. An in-depth discussion of ‘the how’ of 4D BIM is outside the

scope of this work, which is more with concerned the innovation-decision process in construction, and as such now turns to matters of innovation diffusion.

Innovation Diffusion

Diffusion is concerned with the spread of innovations. Various researchers identify the need for greater innovation diffusion research both on the construction industry (Larsen and Ballal 2005) and its projects (Harty 2008). Gambatese and Hallowell (2011b) identify a need for research into the "*identification and dissemination of new technologies, systems and processes that have the potential to become innovations within the construction industry*". These researchers also identify the importance of evaluating the impacts and benefits of innovations, as well as undertaking research into their use in construction. In responding to such calls, Rogers (2003) innovation diffusion theory is used, as a starting point to investigate further.

Rogers (2003) Diffusion of Innovation Theory

Everett Rogers (2003) popularised the 'Diffusion of Innovations' theory of how, why, and at what rate, new ideas and technology spread through cultures. Since its first edition was published in 1962 Rodgers has been cited over 128,000 times, and a brief explanation of several key points and concepts is necessary. Various management and construction scholars who have built upon Rogers work are discussed within a subsequent section. Rogers defines diffusion as the "*process in which an innovation is communicated through certain channels over time among members of the social system*" (2003, p5). Innovation diffusion communication is primarily concerned with new ideas and is identified as being between multiple individuals, as a two-way process. This definition contains all four elements: the 'innovation'; its means of information transfer or dissemination through 'communication channels' (either personal, or non-personal such as mass media); across 'time'; amongst members of a structured set of interrelated units i.e. 'the social system'.

Throughout, several concepts (identified here using italics) and elements of IDT are introduced by Rogers, including:

- How social system members determine the rate of innovation adoption because of the *Perceived Attributes* (characteristics) of the innovation. Specifically, these

- involve its *Relative Advantage; Compatibility; Complexity; Trialability; and Observability*.
- Communication channel effectiveness: Whilst non-personal channels can be effective in mass communication transfer of high value information, in diffusion, individuals place greater emphasis on the subjective judgement of near-peers rather than in experts objective judgements.
 - Classifications within a population, as dependent upon the timing of adoption: *Innovators* (2.5%); *Early Adopters* (13.5%) and the *Early Majority* (34%) are the first 50% of a population reaching a point of critical mass. Following these are the *Late Majority* (34%) and *Laggards* (16%).
 - The norms and rules within a social system as constructed by its individuals and key actors, including *Innovators, Opinion Leaders, and Change Agents*.
 - Classification of adopt-reject decisions, either as discrete-, or connected-decisions: *Optional Innovation-Decisions*, made by individuals, *Collective Innovation-Decisions* made by consensus, and for *Authority Innovation-Decisions*, adoption commitment is imposed by a few controllers or influencers. *Contingent Innovation-Decisions* are when more than one (i.e. connected) individual innovation-decisions are made.
 - Consequences - intended and unintended, positive or negative, of implemented innovations.
 - The innovation-decision process (IDP)² of innovation *Knowledge; Persuasion; Decision; Implementation and Confirmation*, that ultimately leads to innovation adoption or rejection. It is the enhancement of this aspect of IDT that is the focus of this work, with a new contextual model of IDP presented in the results section.

What models are

Models help navigate the complexity of the world by providing a simplified, or idealized representation of some phenomenon, or system. They are abstractions,

²Emmitt (1997) previously considered the applicability of IDT to the UK construction industry also focusing on the IDP, looking at the decisions made in the adoption or rejection of innovative building products. Emmitt's work proposed the notion of 'postponed adoption' which is also used here, where an innovation is not immediately adopted or rejected but knowledge of it is retained for potential future application.

containing assumptions or observations about the relevant, decomposed, elements of a system or real-world situation, useful for purposes such as generating visualisations or simulations, drawing inferences, making predictions, or problem-solving. *“The purpose of the model is not to describe reality but to reduce it to a more manageable form, losing many of the minutiae of reality, but, hopefully, retaining the general form in a way which is more easily understood”* (Raftery 1998). People use them in everyday situations, though they tend not to be thought of as models, with examples including maps, paintings, photographs, diagrams, toys, video games and other computer-generated simulations. Models are used across most academic disciplines. Within the social sciences, conceptual models³, are commonly used for sense-making purposes, to facilitate better understanding, and convey meaning. Raftery (1998, pp.299–300), also suggests models are *“useful only as long as they appear to fit their situation, to describe or analyse a problem adequately. They are useful until they are disproved”*. Where some models fail at points and require complete revision, others merely require refinement or enhancement, so they continue to exhibit likeness to the phenomena being represented.

Building upon Diffusion Research

The enhancement of Rogers IDP model is presented in the results section (Figure 1). Though it has largely been accepted as generalizable across organisational-, marketing-, product-, or process-based innovation-decisions (Windahl *et al.* 2008), it has also faced specific criticisms within the construction management research community. Several researchers (Shibeika and Harty 2015, Lindgren and Emmitt 2017) point out that because of the peculiarities of the sector - it being project-based, structurally complex, risk averse, suffering from short-termism, and bounded by uncertainty (Barrett and Sexton, 2006; Loosemore and Richard, 2015) – for it to be applicable within construction, Rogers’ model requires theoretical extension. Larsen (2005) argues it is *“a practical yet almost over generic theory with inadequate consideration of context”*.

Therefore, several researchers have since built on aspects of Rogers work. Greater focus has been placed on the nature of innovation itself (Dodgson and Gann 2010), to other

³ Raftery (1998) lists a fuller range of model types, in an excellent account of what models are.

IDT components including communication channels, the nature of social systems and the innovation diffusion process (Bass 1969, 2004, Moore 2014). The impact of Rogers' adopter roles and their approximate percentages within a population has also been revisited within general-, and construction-, management literature (Goldenberg and Oreg 2007, Edwards 2014). The most notable additions to diffusion research include the work of Frank Bass who developed a mathematic model helping predict the diffusion of an innovation, and Geoffrey Moore (2014) who contended that, for adoption of disruptive innovations in particular, a 'chasm' must be crossed between the earliest adopters of an innovation and the early majority because of their differing expectations.

A need for further research into construction innovation diffusion

As noted, interest in innovation within the construction environment and project-based organisations has grown since the late 1990's. Miozzo and Dewick (2004) consider there is a scarcity of analyses of innovation within construction. Reichstein *et al.* (2005) advise of too few large-scale surveys of construction innovation. Kale and Ardit (2010) note that from 2004 a surge in construction studies exploring innovation diffusions had occurred, yet few of these used recognised and valid theoretical diffusion models. Prior CM diffusion research includes: investigations into general IDT theory within construction (Larsen and Ballal, 2005); diffusions of managerial innovations, such as: lean construction (Green and May 2005), and; administrative innovations, such as quality management processes (Kale and Ardit 2006). There is much focus on technological innovations including: construction technology (Slaughter 2000) general ICT (Peansupap and Walker 2005, Panuwatwanich *et al.* 2009); CAD (Kale and Ardit 2005); 3D CAD (Tizani 2007); and BIM (Fox and Hietanen 2007, Brewer and Gajendran 2012). Alternative diffusion research efforts have made use of systems dynamics (Park *et al.* 2004), and social network analysis (Larsen 2011). Whilst use of classic IDT remains appropriate for undertaking investigations on innovation adoption in the UK Construction sector, efforts to interrogate it also seem welcome.

Methodology

A mixed-method study informed by a pragmatist philosophy occurred, resulting in a doctoral-programme knowledge contribution. Pragmatism allows for use of mixed methods research (often referred to as the third research paradigm) to address research aims/questions (Johnson and Onwuegbuzie 2004, Morgan 2007). As before, the aims

were to investigate the applicability of classic IDT to the adoption of 4D BIM by the UK construction industry, and; to use a study of 4D BIM diffusion to build upon classic IDT, developing a more relevant model for the construction sector for similar innovations.

The population of interest was those UK construction sector organisations looking to innovate by incorporating BIM/4D BIM within project delivery practices. Relevant individuals, primarily construction planners and project managers representing such organisations therefore became the focus of data collection strategies on a multi-stage non-probability project⁴. Participants were therefore accessed through convenience and purposive sampling strategies. Whilst there are difficulties in quantifying such a population, of the 1,650,000 professionals that Myers (2013) estimates as being directly involved in the delivery of UK construction projects, and following discussions with the CIOB and APM professional bodies, these practitioners can be reasonably assumed to be in the tens of thousands. Regardless, 246 participants were involved overall, with multiple data collection and analysis strategies used across the programme. It contained initial exploratory work, using case study and questionnaire survey research, and latter work employing a second questionnaire survey and this final round of semi-structured interviews with 13 suitable participants drawn from across the programme (qual > quan > QUAN + QUAL). Ethical approval was given by the institutional ethics committee, and deductive research was applied throughout.

Though mixed-methods were used throughout the programme, data were gathered and analysed separately for each distinct phase (e.g. qualitative data was only analysed using qualitative methods and similarly quantitative data was only analysed via quantitative methods), before now, results were not previously synthesized for presentation. However, these mixed methods are now useful for providing what Johnson and Onwuegbuzie (2004) refer to as the 'complementarity' of results (i.e. using results from one method to enhance the results from another method used) within the programme. Previously, findings from an exploratory case study investigating the

⁴ Noting also that from the circa 273,775 related UK 'construction' businesses, or 65,443 registered industry contractors (ONS 2016) there's no way of truly determining how many firms were actively looking to innovate in their approach to project delivery.

consequences of a decision by a large contracting organisation to adopt the use of BIM across all of their future projects were published in Gledson (2016). Then results from two separate questionnaire surveys about the UK construction industry were published, the first investigated the extent and use of 4D BIM in construction planning (Gledson and Greenwood 2016), and the second used classic IDT methods to measure the adoption rate of 4D BIM⁵ (Gledson and Greenwood 2017). Now presenting an enhanced model of the innovation-decision process for modular-technological-process innovations in construction, qualitative findings from the final round of semi-structured interviews are now primarily drawn upon, albeit these findings are reinforced in some places by prior results for purposes of such complementarity.

Results, analysis, discussion

Analysis of results reveals that to better reflect the diffusion of modular-technological-process innovations within the construction sector, several enhancements to Rogers (2003) model are required. Therefore, the IDP for such innovation types follows a similar, albeit amended process explained herein.

A new model of the innovation-decision process

This new model for modular-technological-process innovations, diffusion consists of 6 more involved stages. Each stage and the aspects within them, are now described. Enhancements to the existing model are verified and supported via the findings from the research programme, meaning that 4D BIM and innovation-decisions around its diffusion are used as the vehicle to evidence these. Amendments to Rogers IDP model are shown in Figure 1, with most enhancements shown as black textboxes with white text.

INSERT FIGURE 1 HERE

Figure 1: Enhanced model of the innovation-decision process for modular-technological-process innovations in construction.

⁵ Done using several of the aforementioned IDT elements, and identifying their necessary and sufficient conditions, to determine a rate of 4D BIM adoption amongst construction actors surveyed.

1 Exposure

2 Rogers (2003) initial ‘knowledge’ stage is replaced by two closely related, but distinct
3 stages. At the outset of the IDP, decision-making units (DMUs) are at the threshold of
4 the (I) *exposure* stage, passive in terms of information-seeking behaviours until first
5 exposed to an innovation through communication channels. Thus, the actions of opinion
6 leaders as promoters or gatekeepers of innovation remain important, and at this stage
7 one-way ‘initial innovation messages’ received are either discarded or investigated.
8 Thinking about DMUs as being passive to begin with, challenges an earlier argument
9 that DMUs are instead more active information seekers at this earliest stage of the
10 innovation decision process (Larsen, 2011, p990). Yet interviews here reveal that
11 DMUs first became aware of modular-technological-process innovations only through
12 chance, thereby exhibiting passive, rather than active information-seeking behaviours.
13 Responses suggest that at this threshold, ‘exposure’ occurs because of innovation
14 messages by opinion leaders or change agents, or communications transmitted at work
15 (company briefings) or from educational institutions. Data reveals how exposure also
16 occurs through professional event participation, or via personal networks. Notably, it
17 occurs increasingly, through media consumption. It is worth commenting that the
18 influence of modern media on innovation diffusion within construction, and across
19 society, has expanded enormously since Rogers’ first (1962) and last (2003) editions of
20 ‘The Diffusion of Innovations’. Hence, DMUs can now be inundated with these ‘initial
21 innovation messages’, but not just through traditional print media, or radio or television
22 broadcasts. Exposure now also occurs through web browsing, or via ‘webinars’, or by
23 participating in online groups.

24
25 For 4D BIM, Participant 100 described their initial exposure to it as it: “*Being on*
26 *YouTube clips. Also, it was starting to get talked about in magazines*”. Participant 246
27 discusses how, in terms of innovation (in contrast to getting information from their
28 organisation), online media is ‘up-to-date’, ‘cutting edge’, and “*telling you what’s*
29 *happening now*” (Participant 246).

30 Exploration

31 “*My first knowledge of 4D BIM came through university, and then through my*
32 *studies I learnt what it was. It interested me so I pursued it on my own ... a lot of*

1
2
3 1 *my first knowledge was just through studies and self-interest, rather than being*
4 2 *introduced to it by the company” (Participant 15).*
5
6
7

8 3 Like Participant 15, it is only after ‘exposure’ that DMUs continue through the IDP.
9 4 They enter the (II) *exploration* stage, and depending upon their characteristics and
10 5 perceived needs, they may begin to demonstrate more active information-seeking
11 6 behaviours. The DMU starting the process of formulating a decision, again may choose
12 7 to discard innovation information messages, or may progress to the next stage. Here,
13 8 this model further differs from Rogers’s by recognising that after the initial exposure
14 9 stage, communication channels then involve 2-way acts of communication with *active*
15 10 *information-seeking* performed by DMUs to supplement received messages. At each
16 11 subsequent stage, DMUs continue to seek ‘information messages’, progressing through
17 12 the decision-making process but may still exit the IDP at any stage if experiencing
18 13 discordance. Hence, as shown in this model, communication behaviours of DMUs
19 14 become particularly important from here onwards.
20 15

21 16 Semi-structured interviews reveal that regarding ‘exploration’, participants expressed
22 17 preferences for using internal communication channels because of issues of ‘integrity’,
23 18 ‘trust’, and the importance of two-way communication. Participant 189 called it ‘human
24 19 nature’ and argued that: “... *you’re more receptive and rather ask ‘daft’ questions*
25 20 *[being] prepared to embarrass yourself more easily with people you’ve known for years*
26 21 *... Perhaps you might not in an external environment”*. Participant 210 emphasised that,
27 22 when explored using internal communication networks, innovation information could
28 23 be discussed and challenged, rather than merely being ‘obtained’.
29 24

30 25 From this point on, remaining stages in this IDP model remain as per Rogers’ original
31 26 model, albeit with other enhancements being an additional ‘environmental factor’ (of
32 27 *external agency communications*), and additional ‘decision-action points’ and
33 28 ‘outcomes’. Again, these are typically shown as black text boxes with white text on
34 29 Figure 1 and are discussed throughout.

30 *Persuasion*

31 (III) *Persuasion* occurs when an impression/attitude is created about the innovation.
32 With modular-technological-process innovations such as 4D BIM this research

programme confirms that although Rogers perceived innovation characteristics of 'relative advantage', 'compatibility', 'complexity', 'trialability' and 'observability' still play a role at the persuasion stage, 'trialability' (the opportunity to experiment with, and use the innovation without commitment), and 'compatibility' (between the innovation, and existing infrastructure), and for this particular innovation, certain 'relative advantages' (i.e. in plan communication) are more significant than 'complexity' and 'observability'⁶.

Analysis also reveals how, aside from perceived innovation characteristics, persuasion also occurs. At this stage, the effects of direct communication from relevant external agents upon the innovation-decision environment are most strongly felt. These may also influence or persuade any adoption/rejection decision made. Hence, *external agency communications* also provided further model enhancement.

Key innovation-information messages from Government and other marketplace actors were relevant for 4D BIM diffusion. Examples:

- Within the UK Construction, the UK Government provides the best example of an 'external agent' by combining policy, regulation and championing behaviours (their importance to innovation is recognized throughout the literature, e.g. Gann and Salter 2000, Aouad *et al.* 2010, Caerteling *et al.* 2013, Na Lim 2014). For 4D BIM, Governments role within the 'persuasion stage' of the IDP was summarized by Participant 210: "*if you look at the macro level, Government Strategy provided the focus, and the aim for people, of where to get to. Its gamification of the project environment, gamification of the industry*".
- Another example of how external agency communication affect persuasion comes from marketplace interactions. Data revealed concerns by DMUs around if, and how, competitors were adopting innovation, thus influencing attitudes, and initiating 'imitative' behaviours. Fears usually centred on how their own company is performing, against competitors (i.e. if they are falling behind or

⁶ Gledson and Greenwood (2017) performed inferential tests for 'trialability' and 'compatibility', yielding significant, Fisher's Exact Test Statistics of .005, and .026 respectively.

being expected to be using it)⁷. For 4D BIM, this was evidenced by Participant 189, reflecting upon an experience attending ‘post –tender interviews’:

“... we took our 3D model along, to show site logistics and sequence, to demonstrate that we understood the works, the problems, and tried to find solutions. We thought it would go down very well, but the feedback was that the other three tenderers had something similar. So now, if you went, and you didn’t have something like that, you would look inferior, even if your ideas were good. It’s almost as if it’s now expected of you”.

Decision

(IV) *Decision* stage occurs when a DMU adopts or rejects the innovation. In Rogers model, only four outcomes were listed, that: Initial decision to adopt is followed by ‘continuous adoption’ or later ‘discontinuance’ of the innovation, or; initial decision to reject can be followed by ‘continuous rejection’ or by ‘later adoption’. This enhanced model however reveals that in the construction sector it is more likely that for *modular-technological-process innovations* one of five more nuanced ‘outcome types’ occurs. The most typical outcomes are *gradual-adoption*, *postponed-adoption*, or *passive-rejection*, and rarer outcomes include *immediate-adoption* or *outright-rejection*. Owing to the project-based nature of construction, any adoption decision made is usually a ‘postponed-adoption’, or a ‘gradual-adoption’ decision. This is because ‘if and when’ adoption decisions are largely related to the timing and requirements of individual projects. Complementary results from Gledson and Greenwood (2017) reinforce this, evidencing that for 4D BIM, the usual time lag reported between first awareness and adoption was between 28.5–36.0 months. This supports the model enhancements that innovation adoption in construction is more typically ‘gradual’ or ‘postponed’ but rarely ‘immediate’⁸.

⁷ Whilst such concerns may apply to 2nd/late ‘movers’, other organisations considered as innovators/early adopters (i.e. ‘first movers’), were found to have their own concerns around trying to actively restricting innovation communications and marketplace interactions. These were organisations that had positioned themselves to offer ‘differentiation’ to clients through a unique selling proposition (USP) and providing business benefits derived from innovate behaviours appear to act differently. For this reason, the data suggests that such organisations become much more internally focused to retain that competitive advantage.

⁸ Gledson and Greenwood (2017) show that whilst 63.0% of respondents confirmed 4D BIM use/awareness of use from someone in their organisation, only 9.8% adopted and used 4D BIM ‘immediately’, i.e. within the same year of recorded first awareness.

‘Postponed-adoption’ is an innovation concept from Emmitt (1997), and for modular-technological-process innovations, this could involve the need to wait for the next-, or target a suitable future-, project before adopting. This was described variously by Participant 189: “*you maybe come across a project where you think ‘oh, this innovation might work for that’, but it is very ad-hoc*”, and then by Participant 123: “*it’s just trying to find the right opportunities to bring them to use. [A project] might come in tomorrow but it might not be for 2 years, where I can actually see a use for it*”.⁹ Alternatively ‘gradual-adoption’, a new concept introduced here, may occur. **This involves trialling the innovation¹⁰** on selected projects before rolling it out further, perhaps in an extended trial. In this outcome, trials are conducted without commitment to fully adopt the innovation, yet if organic organisational adoption occurs then the innovation becomes part of accepted practice. Reinforcing this, Participant 41 provides example of how gradual adoption occurs, and how it is constrained by sector norms:

“We tend to want to trial innovations on one project ... we get this long cycle where we develop an innovation, we trial it on a project for between 12-24 months, and only at the end do you gain the learning. Then they probably want to trial it on 4 or 5 [other] projects simultaneously. At the end of those it may then get rolled out across the business, so its anywhere between 2-4 years to deliver an innovation across the whole workplace. The reason that this ends up happening, is that profit margins are quite low, and we are a very risk adverse industry. Those two things combined with long lifecycles mean that innovation is ... it’s not stifled but it is extremely hard to drive through, and because we’ve never done dramatic change, it’s very much tiny incremental steps because of the risk involved, so it slows the effect, and that’s an industry-wide thing”.

If conversely, the decision is to reject the innovation, or do nothing, then ‘passive-rejection’ most typically occurs. Rarer outcome types include ‘immediate-adoption’,

⁹ Several participants considered how the ‘innovation source’, impacts upon the timing of when an innovation is adopted. Participant 123: “*its subcontractors and suppliers that are bringing these new ‘products’ to the market, so it’s trying to find the right project to get them implemented on*”.

¹⁰ And with a Fisher’s Exact Test Statistics of .005, the significance of being able to trial innovations within the sector was previously established and discussed in Gledson and Greenwood (2017).

and ‘outright rejection’, although these appear infrequent with modular-technological-process innovations. To reinforce how rare ‘outright rejection’ is, attention is drawn to results in a complementary study (Gledson and Greenwood (2017) against question ‘Please confirm if a decision has been made to adopt or reject the use of 4D BIM for the planning of construction work’. Of three response options offered: ‘adopt’, ‘reject’ and ‘undecided/no decision made’. Only 1% of respondents, confirmed definite ‘reject’ decisions. Hence, regarding innovation diffusion, it can be determined that for modular-technological-process innovations ‘passive rejection’ i.e. making no definitive adopt/reject decision, occurs more frequently than outright rejection decisions. It’s also true that when a ‘passive rejection’ outcome occurs, this may be followed by later gradual-, or postponed-, adoption outcomes.

In addition to decision outcome types, this related study reveals a further factor of organisational size, which affects the firmness of the actual decisions made within the ‘decision’ IDP stage. Gledson and Greenwood (2017) reveal that for *modular-technological-process innovations*, the most frequent type of adoption-decisions made are ‘authority decisions’ (by organisational upper management), followed by ‘collective decisions’ (by consensus), with the least frequent being ‘optional decisions’. In that work, bivariate analysis demonstrated associations between company size and the types of organisational decisions made¹¹, revealing that innovation adoption decisions in larger companies (250 persons+) are much more likely to require ‘authority-decisions’. For 4D BIM these researchers also established that, there is more likely to be personal use of 4D BIM within larger companies¹². One inference drawn from this complementary work is that a definite ‘authority-decision’ within organizations, leads to quicker personal adoption/use of the innovation by staff members¹³. These definite ‘authority-decisions’ within larger companies were referred to throughout by participants working for such companies, several of whom, also implied gradual-, or postponed-, adoption for 4D BIM:

- “They definitely said yes we are going to adopt it” (Participant 203).
- “The initial decision was to adopt it. It wasn't ever rejected” (Participant 41).

¹¹ Resulting in a Fishers Exact test statistic of .019.

¹² Fishers Exact test statistic of .001.

¹³ Though Gledson (2016) reports that despite such definite ‘authority decisions’ being made by large organisations, variances still exist between individuals in terms of adoption/use.

1 ▪ *“The corporate decision was to adopt ... to commit the resources and time*
 2 *necessary, because of the recognition we needed to do it to remain competitive”*
 3 (Participant 189).

4 ▪ *“The decision was made that it was useful, and we would develop it further”*
 5 (Participant 123).

6 In contrast, analysis also revealed how smaller and medium sized decisions can be more
 7 flexible to offering ‘immediate-adoption’ decisions: *“After [principal] first used it ... it*
 8 *became an adoption decision. Because he ran the company, it's a small company, he*
 9 *could make the decision quickly”* (Participant 245). However, the data also show how
 10 decisions can be less firm, producing ‘passive-rejection’ outcomes, and slowing levels
 11 of individual adoption and use: *“It definitely wasn't a rejection, but it was very, almost*
 12 *an arm's length thing, they kind of just let me get on with it, they paid for the software*
 13 *and the training course [...] and it was 'oh yes, that seems like a good idea'. It wasn't*
 14 *rejected outright, but it also wasn't adopted by the group. Just, something where they*
 15 *said “yeah, ok, you go away and do it”*” (Participant 100).

16 *Implementation*

17 If the decision is to adopt a modular-technological-process innovation, this will be
 18 followed by (V) *implementation*, where the process of the innovation being used, begins
 19 via either full adoption, or by trial. Rogers (2003) confirms this process continues until
 20 the innovation is institutionalised, no longer being considered as new/distinct from
 21 regular business operations. Success at implementation stage is subject to much
 22 organisational uncertainty, not least because those who have made decisions to
 23 implement, are often different from the implementers. It's important to note that though
 24 organisational attributes appear to be more important than individual attributes,
 25 implementers themselves should not be considered to be mere passive acceptors of
 26 innovation-decisions. Whilst there may be enthusiastic adopters, there may also be those
 27 that resent being directed to adopt an innovation, therefore seeking to challenge or
 28 discredit it.

30 Whilst 4D BIM adopters have shown appreciation and enthusiasm for its benefits, a
 31 related exploratory case study (Gledson 2016) undertaken during an implementation
 32 stage following an authority-decision (that all future company projects use BIM),
 33 revealed fears and concerns of organisational staff reinforced in this round of

1 interviews. Specifically, that in terms of general innovation implementation: there are
2 people issues in terms of individual abilities to use, and commitment toward, such
3 innovations¹⁴; that productivity reduces during learning curves¹⁵ (may not be
4 recognised, or understood by upper management); and that use of such innovations
5 creates additional work requiring additional resource)¹⁶. Additionally, analysis reveals
6 how innovation implementation can also lead to inefficient effort duplication¹⁷.

7
8 Such concerns reinforce why ‘trialability’ of modular-technological-process innovations
9 is important, hence this new model also shows additional ‘action point’: *Trial*
10 *Innovation*. In construction, trials occur on individual projects, or on a series of projects.
11 For trials to be considered successful they are reviewed post-project, with results, as
12 determined by measurable success criteria, analysed to determine if ongoing adoption
13 continues. Participant 41 explains this, variously describing his prior experiences as a
14 ‘change agent’ working for a software vendor promoting 4D BIM:

15 “[Vendors] spend a lot of time giving impressions of the provable benefits, and the
16 industry takes them with a pinch of salt, wanting to try for themselves. I found the
17 best way is, you end up trialling on a single pilot project, setting very clear goals
18 of ‘this is what success/ failure looks like’ and you then score it, as very criteria
19 driven. [So] trial it, but if it meets the measured criteria, then it works, there is no
20 need for that middle second phase of ‘well let’s trial it across 5-10 projects now’.

21
22 One of the last experiences I had with [Software Vendor], we went from doing a
23 couple of very small pilots in isolation to then doing ... they called it an extended
24 pilot, but it became the beginnings of a mass roll-out, though it was structured in
25 such a way if that had failed, as part of a larger pilot the roll out would have
26 stopped at the 10 projects. The minute it crossed the 10-project threshold it became

¹⁴ “It’s culture, you need people who want to try and learn something different, with the correct attitude, who understand the possible benefits ... It’s just about changing people’s attitudes” (Participant 3).

¹⁵ “You’ve got this learning curve they go through before they become proficient at it and we all start seeing the benefits” (Participant 183).

¹⁶ “It is incredibly resource intensive to develop and then maintain a 4D model” (Participant 208); “4D is great, but it requires intense effort to create and update which makes it a proposition of: ‘Is it worth the effort to create and maintain?’” (Participant 163).

¹⁷ Gledson (2016) illustrates such effort duplication in the hybrid project-delivery processes employed during early BIM innovation adoption.

1 1 *'this is the way we are doing things from this day forth'. In reality, if you trace it*
 2
 3
 4 2 *back it was because of this 1 successful pilot project".*
 5
 6
 7

8 3 It's also expected at this stage that some 're-invention' may occur where an innovation,
 9 4 or its use, may be modified or altered to suit the needs of the various adopters. In this
 10 5 study it was implied that 4D BIM use was 're-invented' by several construction project
 11 6 practitioners for their own purposes: *"it's not just used by planners. It's also used by*
 12 7 *construction managers, and by the commercial guys, it's used by everyone ... It's used*
 13 8 *by people for different purposes"* (Participant 193). Rogers (2003) advises that such
 14 9 reinvention leads to a faster rate, and higher sustainability of an innovation.
 15
 16
 17
 18
 19
 20

21 10 Confirmation

22 11 The final stage (VI), *confirmation* occurs when a DMU tries to obtain 'reinforcement'
 23 12 regarding *made* decisions, although it is possible that seeking such reinforcement may
 24 13 lead to subsequent rejection of the innovation *because* of new information. This model
 25 14 shows two further enhancements here. The first addition identifies that 'reinforcement
 26 15 messages' are sought by the DMU at this stage to supplement any prior innovation
 27 16 information messages received. The second addition is the 'action point': *Measure*,
 28 17 referring to the measurement of data relevant to predetermined success criteria. These,
 29 18 along with the means of measurement, should be devised at implementation stage.
 30
 31
 32
 33
 34
 35
 36
 37
 38

39 20 For 4D BIM, the importance of undertaking such measurement during trialling was
 40 21 revealed¹⁸ Unfortunately, at the time of the study, because of project duration
 41 22 timescales, few if any, organisations seemed to have moved beyond implementation
 42 23 stage, to the confirmation stage, though some had begun to consider means of
 43 24 measurement: *"We are not at the stage of being able to measure benefits of it. We are*
 44 25 *just on the learning curve of how to implement it. I would say that once we have*
 45 26 *completed that learning curve, then we can start measuring output data, and see if it*
 46 27 *has improved against our traditional output data [...]* Until we implement 4D regularly
 47 28 *we won't be able to measure it and do a comparison"* (Participant 15).
 48
 49
 50
 51
 52
 53
 54
 55
 56

57 18 See earlier comment by Participant 41 regarding 'trialability' regarding the importance of:
 58 "setting very clear goals of 'this is what success/ failure looks like' and you have to score it, but
 59 it has to be very criteria driven ... [so] its - trial it, but if it meets the measured criteria then it
 60 works".

1 Conclusion.

2 Construction is often criticised for poor project delivery, for not innovating, and for not
3 delivering the types of process improvements seen in other industries. However, there is
4 now evidence that parts of the sector have begun to address these concerns and improve
5 some processes. For example, constructors wishing to improve the time predictability of
6 their projects, and who understand the benefits arising from using 4D BIM could use
7 these findings to manage a more focused adoption and implementation of this
8 innovation type in their construction planning practices. Because, as a minimum, the
9 advantages of being able to communicate the construction plan using 4D methods rather
10 than traditional formats mean that this innovation is worth adopting. Yet whilst there is
11 a maturing knowledge base relating to BIM as an innovation, only some of this
12 concerns issues around its adoption, as related back to classic theory, such as innovation
13 diffusion theory (IDT). For related innovations such as 4D BIM, classified here more
14 broadly as a modular-technological-process innovation, this gap is even more apparent.
15 This study addressed this, presenting an enhanced model of the innovation-decision
16 process specific for the construction sector. This can aid understanding of innovation
17 adoption in the UK construction industry as specific to these innovation types by
18 practitioners, and by scholars. First, explanation and discussion over the importance and
19 use of models to facilitate understanding was provided. Then, the generalisability of
20 Rogers (2003) IDP model, was discussed, whilst highlighting construction-centric
21 criticisms of it. Finally, Rogers IDP model was built upon, adding stages, decision-
22 action points, and outcomes, to produce an enhanced model specifically for modular-
23 technological-process innovations in the construction sector. These enhancements were
24 explained, and verified using the results of a multi-stage, mixed-method, research
25 programme. In this way, the objective of using a 4D BIM study to develop a model that
26 further informs innovation diffusion theory was addressed. This new model can assist
27 practitioners in their future adoption/rejection decisions for any such modular-
28 technological-process innovations. For scholars, by extending generic attributes of the
29 IDP model into a construction specific context, it provides greater relevance and also
30 addresses the need for a construction specific model via its theoretical extensions. In
31 addition to these enhancements, this model also reinforces, both for scholars, and
32 practitioners, the importance of existing diffusion concepts of compatibility and
33 trialability, for such innovation types.

1 *Limitations*

2 The overall research programme was a mixed-method study informed by a pragmatist
3 philosophy combining qualitative findings from an initial case study, with quantitative
4 findings from two structured questionnaires, and this final round of semi-structured
5 interviews providing the present qualitative data. The limitation with the greatest
6 potential impact relates to the sampling frame used for the quantitative parts of the prior
7 stages of this study. Instead, because this final stage focused on persons interested in the
8 subject matter, purposive sampling methods were used. These final interviews were
9 held with persons assessed as being suitable, who, having completed the second
10 questionnaire, had therein also signalled willingness to participate in follow-up
11 interviews. From a pragmatist perspective, in mixed methods research such participant
12 selection is not considered a weakness. However, if the quantitative elements only were
13 considered in isolation, use of the non-probability sampling frame may lead readers to
14 believe the ability to make any generalisations¹⁹ at all about this population is restricted.
15 Also from the pragmatist perspective, but as regards the integrity of the conclusions,
16 this work has achieved pragmatic validity (Worren *et al.* 2002), and its context relevant
17 findings are ecological valid. Over the course of the mixed-method research
18 programme, such pragmatic validity was also achieved using strategies of triangulation
19 and member-checking to verify the credibility, transferability, and dependability of the
20 findings. In doing so, the study achieved its ultimate aim of developing a more relevant
21 model for the construction sector, and its actors.

23 *Future research recommendations*

24 To advance this research, efforts should concentrate on the IDT contributions made.
25 Subsequent research focussing on modular-technological-process innovations could
26 make use of the enhanced innovation-decision process model, applying, testing, or
27 further validating it. Any focus on the initial exposure and exploration stages, using

¹⁹ Noting that, whilst in pragmatic science, validity does not contain the same connotations as in pure quantitative research, aside from generalisability, discussions of validity from a purely (post)positivist quantitative research perspective usually discuss other facets such as measurement-, internal-, and external-, validity. An excellent account of (post)positivist validity in the construction domain is provided in the work of Karakhan and Gambatese (2017) and Zhang and Mohandes (2020).

1 qualitative methods, could generate further knowledge about these. Efforts directed
2 toward the decision, implementation and confirmation stages remain equally important.
3 Similarly, the five decision-outcome types discussed in this model also warrant further
4 research, and survey research could reveal more about the frequency, and reasons
5 behind these types. Organisational efforts to trial, measure benefits, and capture
6 learning around such innovations, would be valued and potentially being achieved
7 through case study research.

	246	M	-	Planner	Middle management level

Research Instrument: Semi-Structured Interview Guide

The first few questions 1-3 focus on innovations and the construction industry in general. An innovation is defined as “an idea, practice or object that is perceived as new by an individual or other unit of adoption”, after that a few questions focus on specific innovations of BIM and 4D BIM. The last question relates to construction project time predictability.

- 1) What is your assessment of the level of innovation in the construction industry?
- 2) Does the way that the industry is structured affect the levels of construction innovation?
- 3) How are industry innovations best implemented?

About BIM in general:

- 4) Has BIM impacted upon the quality of production information?
- 5) Has BIM impacted upon the planning of construction work?

The rest of the questions focus particularly on 4D BIM. First please review the below model and text describing the 5 stages of the Innovation decision process.

The innovation-decision-process is the process through which an individual (or other decision-making unit) passes from first knowledge of an innovation to forming an attitude toward the innovation, to a decision to adopt or reject, to implementation of the new idea, and to confirmation of this decision.

- 6) You identified in the prior questionnaire when you were first aware of 4D BIM and when you first used it (the knowledge (I) and decision (III) stages respectively). I'd like to explore some further aspects of this 'innovation decision' period in line with the above model: For example, (I) what was your initial knowledge of 4D BIM; (II) what persuaded you to consider the use of 4D BIM; (III) what initial decision was made after first use - adoption or rejection; (IV) any issues around the implementation - when it was put into actual practice; and (V) has any confirmation occurred to reinforce the adoption / rejection decision made.
- 7) On the questionnaire you have already identified the impact of communication channels upon your use of 4D BIM. As a reminder these communication channels are external (such as mass media - internet, literature etc.) and internal (such as interpersonal - face to face exchanges between two or more individuals) communication channels. Could you expand further on your original answers?
- 8) Key persons involved in any innovation diffusion effort are opinion leaders and change agents. An opinion leader is someone internal to your company or network who provides information and advice about innovations often in an informal role. A 'change agent' is someone external from your company or network who acts as a link between the generators of an innovation and any potential adopters of an innovation. In this instance a change agent may be someone who acted as a link in-between government task force or software vendors and yourself. Can you recall any particular interaction with individuals who fit these descriptions, and how this interaction impacted upon the innovation-decision process?
- 9) There are always consequences (changes) that occur as a result of adoption or rejection of an innovation I'd like to explore these. Can you tell me of any (I) desirable or undesirable consequences (II) direct or indirect consequences and (III) anticipated or unanticipated consequences of 4D BIM innovation?
- 10) The UK government has set a target for 2025 that all construction projects are to be delivered 50% faster (from inception to completion) than the industry 2013 performance, where only 45% of projects were delivered on time or better. Do you think the use of 4D BIM can help improve the time predictability of construction projects? And if so how?
