## 18 ABSTRACT

19 Foam rolling (FR) durations totaling  $\leq 60$  seconds per muscle are reported to acutely increase  
20 flexibility and vertical jump performance. However, limited research has investigated whether  
21 these benefits can outlast the inactive post-warmup preparatory period that typically separates  
22 warmups from the start of sporting competition. 11 male athletes (height  $1.77 \pm 0.09$  m, body  
23 mass  $78.0 \pm 17.0$  kg, age  $22 \pm 2$  years) completed familiarization, followed by 3 experimental  
24 trials in a randomized and counterbalanced repeated measures crossover design. Trials  
25 commenced with 5 minutes of jogging, before ankle dorsiflexion range of motion (ADF-  
26 ROM), sit and reach (S&R), countermovement jump (CMJ), and squat jump (SJ) baseline  
27 testing. Participants then sat inactively for 10 minutes (control) or performed lower extremity  
28 FR totaling either 30 (30 FR) or 60 seconds (60 FR) that targeted four agonist-antagonist leg  
29 muscles. Testing was then repeated before and after a simulated inactive 15 minutes post-  
30 warmup preparatory period to establish the acute and delayed effects of FR on performance. A  
31 two-way repeated measures analysis of variance was used to identify any significant interaction  
32 effects between conditions (30 FR, 60 FR, control) and timepoint (baseline, acute, delayed).  
33 No significant condition x timepoint interaction effect was detected for the ADF-ROM ( $f =$   
34  $1.63, p = 0.19$ ), S&R ( $f = 0.80, p = 0.54$ ), CMJ ( $f = 0.83, p = 0.99$ ), or SJ ( $f = 0.66, p = 0.99$ ).  
35 Therefore, FR totaling  $\leq 60$  seconds appears insufficient to enhance flexibility or vertical jump  
36 performance in male athletes.

37

40 Jump, Squat Jump.

## 41 INTRODUCTION

42 Foam rolling (FR) applies external compression onto the fascia that surround  
43 musculotendinous units<sup>1</sup>. This external compression has been shown to alter muscle and  
44 tendon compliance, with superior joint flexibility<sup>2-6</sup> and performance across vertical jump,  
45 linear speed, and multidirectional agility testing reported in some studies following FR<sup>7,8</sup>, but  
46 not always in others<sup>9-12</sup>. These potential benefits suggest that FR could complement sporting  
47 warmups, but little consensus exists on the minimal FR duration necessary to elicit any  
48 potential benefits<sup>13</sup>. Additionally, to enhance subsequent sports performance, the minimal  
49 duration of FR must elicit acute benefits that can outlast an inactive post-warmup preparatory  
50 period, which typically separates a warmup from the start or restart of competition<sup>14</sup>. Such  
51 inactive periods may impair sports performance by decreasing core and muscle temperature,  
52 with periods as short as 15 minutes significantly decreasing both muscle temperature and  
53 subsequent sports performance<sup>14,15</sup>.

54

55 Multiple studies concur that FR durations totaling  $\geq 90$  seconds per muscle, which are typically  
56 performed by completing multiple shorter sets (i.e., 3 x 30 seconds), appear to increase  
57 flexibility of the hip<sup>4</sup>, knee<sup>6</sup>, and ankle<sup>5</sup>. In addition, one study using roller massage, a similar  
58 technique to FR, reported isometric maximal voluntary contraction (MVC) torque increased in  
59 the tibialis anterior<sup>16</sup>. Mechanisms proposed to explain the increased joint flexibility are the  
60 generation of heat caused by the friction created during FR, and the application of mechanical  
61 stress from FR onto the fascia<sup>17</sup>. This might cause the fascia to change from a more viscous  
62 and solid resting state, into a compliant state that promotes greater flexibility<sup>17</sup>. In addition,  
63 FR might cause phosphorylation of the myosin regulatory light chains, providing a potential  
64 mechanism that explains the observed increase in MVC torque<sup>16</sup>. Importantly, following 20  
65 minutes of inactivity, acute improvements in ankle dorsiflexion have been reported to remain  
66 above controls performing no FR<sup>5</sup>. Therefore, performing FR totaling  $\geq 90$  seconds has been  
67 shown to elicit benefits, such as enhanced flexibility, which persist between the warmup and  
68 start/restart of competition. The ecological validity of spending  $\geq 90$  seconds per muscle group  
69 in a time constrained warmup however remains questionable. Nevertheless, it is less known  
70 whether the same acute benefits can be elicited with FR durations totaling  $< 90$  seconds per  
71 muscle group. A review of 73 papers suggests this might be possible, advising that FR for 3 x  
72 30-120 seconds per muscle appears most optimal for increasing flexibility<sup>18</sup>. This is important  
73 because understanding the minimal FR duration necessary to induce positive acute effects  
74 could assist practitioners to optimize pre-competition and halftime practices.

75

76 The acute effects of FR totaling  $< 90$  seconds remains equivocal, with little research so far  
77 investigating whether  $< 90$  seconds can outlast an inactive post-warmup preparatory period.  
78 Studies examining both recreational individuals and competitive athletes have highlighted little  
79 to no improvement in knee extension or quadriceps flexibility after 60 seconds of FR<sup>11,12</sup>, nor  
80 superior vertical jump height<sup>2,9,10</sup>. However, within collegiate athletes, hip flexibility  
81 significantly increased following 60 seconds of FR<sup>2</sup>, and vertical jump height significantly  
82 improved following FR totaling 30 seconds<sup>8</sup>. Furthermore, just 10 seconds of roller massage,  
83 has been reported to increase sit and reach test performance with no detrimental effect on  
84 hamstring MVC torque<sup>19</sup>. Such contradictory findings therefore make the acute effect, and  
85 especially the delayed effect beyond any inactive post-warmup preparatory period, of FR  
86 totaling  $< 90$  seconds inconclusive.

87

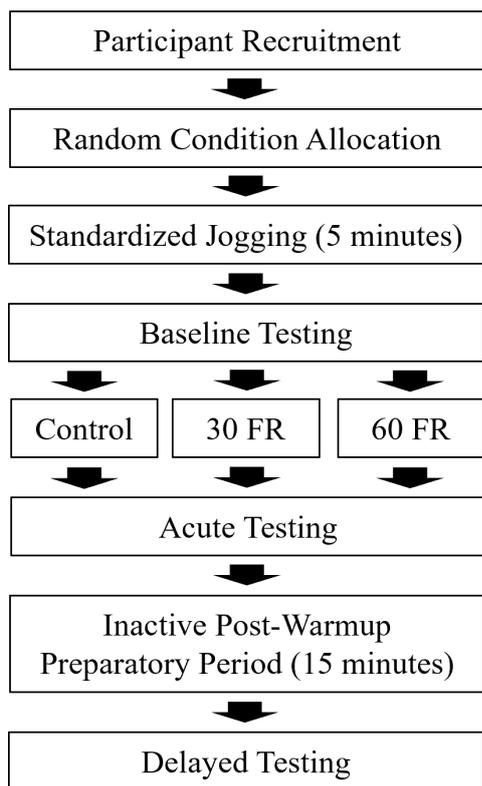

88 The discrepancies between research implementing shorter durations of FR activity on  
89 performance could be attributed to the targeted muscle groups. Research reporting improved  
90 flexibility following FR totaling <90 seconds per muscle targeted agonist-antagonist muscle  
91 pairs <sup>2</sup>, while most studies found little to no effects when targeting only the antagonists <sup>11,12</sup>.  
92 The improved flexibility might theoretically have resulted from reciprocal inhibition, a  
93 phenomenon whereby targeting agonists results in the inhibition of antagonist motoneurons to  
94 increase joint flexibility <sup>20</sup>. This reciprocal inhibition was previously suggested to contribute to  
95 improved flexibility following agonist-antagonist FR totaling 180 seconds <sup>3</sup>. Therefore, given  
96 the proposed efficacy of agonist-antagonist FR, further investigation is required to establish  
97 the effect of shorter FR durations (<90 seconds per muscle), with a specific focus on agonist  
98 antagonist muscle pairs. Additionally, despite some studies reporting FR totaling <90 seconds  
99 acutely improved vertical jump height <sup>8</sup>, it remains unknown if any benefit from FR of reduced  
100 durations can outlast a typical inactive post-warmup preparatory period. Therefore, the aim of  
101 this **exploratory** study was to investigate the acute effects of short FR durations on flexibility  
102 and vertical jump performance, as well as whether any acute effects could outlast a simulated  
103 inactive post-warmup preparatory period of 15 **minutes**.

104

## 105 METHODS

### 106 Design

107 A repeated measures crossover design was employed (figure 1). Participants completed one  
108 familiarization and 3 experimental trials between 1900 and 2030 hours, which were each  
109 separated by at least 48 hours rest. Familiarization involved completing one trial utilizing an  
110 identical protocol to the experimental trials. Experimental trials began with 5 minutes of  
111 jogging at a standardized pace, before a flexibility and vertical jump testing battery (baseline).  
112 This testing battery was performed in the fixed order of ankle dorsiflexion range of motion  
113 (ADF-ROM), sit and reach (S&R) for hip and lower back flexibility, countermovement jump  
114 (CMJ), and squat jump (SJ). Such fixed ordering adhered to recommendations from the  
115 National Strength and Conditioning Association to perform flexibility testing before vertical  
116 jump testing <sup>21</sup>. Participants were then randomized into 3 groups that performed total FR  
117 durations of 0 (control), 30 (30 FR), or 60 seconds (60 FR) in a counterbalanced order across  
118 the experimental trials. The testing battery was then immediately repeated to identify any acute  
119 effects of FR (acute), which was then followed by participants remaining seated for 15 minutes  
120 to simulate an inactive post-warmup preparatory period. The testing battery was then repeated  
121 immediately after the simulated post-warmup preparatory period (delayed), to establish  
122 whether any acute effects from FR could outlast 15 minutes of inactivity. For all testing, the  
123 maximum score from 3 recorded attempts was used for statistical analysis.

124

125 *Figure 1. Study flow chart.*

126

127 **Participants**

128 The study received institutional ethical approval from the Northumbria University Health and  
 129 Life Sciences Research Ethics Committee and was conducted according to the Declaration of  
 130 Helsinki. After receiving verbal and written explanation of the study, a **convivance sample of**  
 131 11 male athletes (stature  $1.77 \pm 0.09$  m, body mass  $78.0 \pm 17.0$  kg, age  $22 \pm 2$  years,  $\geq 6$  months  
 132 amateur boxing experience) provided their written informed consent to take part. All  
 133 participants had no current lower extremity injury nor any experience of undertaking structured  
 134 FR. Participants also completed current UK physical activity guidelines of at least 150 minutes  
 135 moderate or 75 minutes vigorous weekly aerobic activity <sup>22</sup>. **This physical activity included**  
 136 **averaging at least two boxing training sessions each month, but participants did not perform**  
 137 **structured resistance training.**

138

139 **Procedures**

140 All groups performed an initial warmup of jogging around a 10 meters<sup>2</sup> (m<sup>2</sup>) square marked  
 141 out with cones for 5 minutes. The speed was standardized by an online metronome  
 142 (8notes.com, Red Balloon Technology Ltd, St Albans, UK) to 132 beat/min, by instructing  
 143 participants to coincide their steps with the beat.

144

145 Following the initial warmup, 3 attempts at each baseline flexibility and vertical jump test were  
 146 performed. All measures of flexibility were performed wearing no footwear, and vertical jump  
 147 tests were completed in the same footwear between trials. **The ADF-ROM test was performed**  
 148 **from a standing position. To perform this,** participants placed their longest toe, either the hallux  
 149 or second toe, against a wall and then flexed the corresponding knee until it contacted the wall

150 <sup>23</sup>. The longest toe was then moved progressively further away from the wall until the knee  
151 could not flex for the patella to touch the wall. The furthest distance between the longest toe  
152 and the wall, where knee flexion could still enable the patella to touch the wall, was measured  
153 to the nearest 0.1 centimeter (cm). This was done using an inextensible tape measure placed  
154 perpendicular to the wall, with all readings taken from the most distal aspect of the longest toe.  
155 **Attempts were excluded if the participants heel lifted off the floor.** For the S&R test,  
156 participants placed their feet at the base of a S&R box (Cranlea, Birmingham, UK). Whilst  
157 keeping both knees extended, participants reached forward with interlocking hands. **Both hip**  
158 **and spinal flexion were permitted**, with the furthest distance reached then recorded to 0.5 cm  
159 <sup>24</sup>.

160

161 Vertical jump testing was measured to 0.1 cm **using the flight time method** of an Opto Jump  
162 (Microgate, Bolzano, Italy), which was connected to a laptop computer (Idea Pad 510, Lenovo,  
163 North Carolina, USA) running Opto Jump Next (Microgate, Bolzano, Italy). Participants  
164 started with their feet approximately shoulder width apart and hands placed on hips. During  
165 the CMJ, participants squatted to a self-selected depth (established during familiarization)  
166 before immediately jumping vertically for maximum height. For the SJ, participants squatted  
167 to a 90° knee angle that was measured by a goniometer (Cranlea, Birmingham, UK)  
168 **approximately using the lateral malleoli and greater trochanter**. This position was held for 3  
169 seconds, before jumping vertically for maximum height. During both CMJ and SJ jumps,  
170 participants were instructed to maintain knee and hip extension during flight, with slight knee  
171 and hip flexion permitted upon landing. **Participants were also verbally instructed to “jump as**  
172 **high as possible” and a concrete floor was used for both jumps.** Jumps were excluded if the  
173 participant’s hands did not remain on hips, or flexion of the hips or knees occurred during the  
174 flight phase. **SJ attempts were also excluded if the participant performed a slight**  
175 **countermovement prior to take off.**

176

177 Following the initial warmup, baseline flexibility, and vertical jump tests, FR conditions were  
178 performed with a Grid Foam Roller (Trigger Point, Porcheville, France) targeting muscles in  
179 the fixed order of left then right gastrocnemius, hamstrings, quadriceps, and tibialis anterior.  
180 Muscles were targeted unilaterally, with the non-targeted limb being placed above the targeted  
181 limb to maximize compression. During FR, participants placed both hands on the floor for  
182 stability, and moved their body forwards and backwards over the foam roller. This movement  
183 speed was standardized by the online metronome to 40 beat/minutes and the participants were  
184 encouraged to maintain their full body mass over the foam roller whilst performing FR. The  
185 30 FR condition involved two sets of 15 seconds per muscle (4 minutes total FR), while the 60  
186 FR condition involved two sets of 30 seconds per muscle (8 minutes total FR). The control  
187 condition involved participants remaining seated for 10 minutes.

188

189 The reliability of each test was determined prior to formal testing during a pilot study (Table  
190 1). 6 male participants (height  $1.74 \pm 0.11$  m, body mass  $75.3 \pm 10.5$  kg, age  $25 \pm 8$  years),  
191 completed 2 trials separated by 48 hours. These trials involved completing 5 minutes of  
192 standardized jogging and then one testing battery, both using identical procedures as described  
193 above for ADF-ROM, S&R, CMJ, and SJ. Test-retest reliability was then determined through  
194 calculating typical error as the standard deviation of the difference score between trials divided  
195 by the square root of 2 <sup>25</sup>.

196

Table 1. Inter-trial typical error for each test determined from 2 trials separated by 48 hours inactivity, as well as group averages from each trial.

Test	Trial 1 (cm)	Trial 2 (cm)	Inter-Trial TE (cm)
ADF-ROM distance	9.3 ± 3.8	9.7 ± 3.2	1.8
S&R distance	20.8 ± 5.1	19.4 ± 6.4	1.5
CMJ height	31.8 ± 7.7	33.7 ± 6.5	1.4
SJ height	30.4 ± 6.8	30.6 ± 4.7	1.7

*Note.* Trial 1 and 2 values are  $M \pm SD$ , TE = typical error, ADF-ROM = ankle dorsiflexion range of motion, S&R = sit and reach, CMJ = countermovement jump, SJ = squat jump.

197

## 198 Statistical Analyses

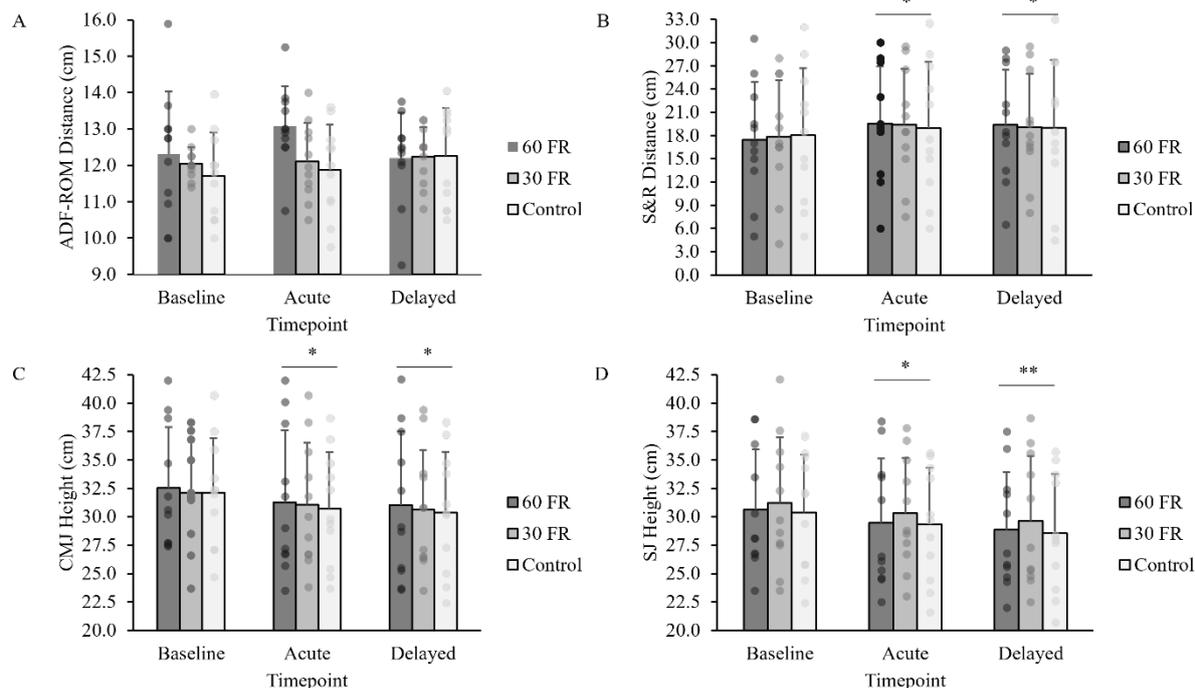

199 Statistical analyses were conducted using SPSS (SPSS Statistics v26, IBM, New York, USA),  
 200 with significance set at  $p < 0.05$ . Normal distribution of data was confirmed using the  
 201 Kolmogorov–Smirnov test. A paired sample t-test identified no difference between the left and  
 202 right leg ADF-ROM at baseline ( $p = 0.65$ ). As a result, the mean of the right and left leg was  
 203 used during subsequent analysis. Sphericity was assessed using Mauchly’s test, with non-  
 204 violations interpreted using assumed sphericity and violations interpreted with Greenhouse-  
 205 Geisser corrections. A two-way repeated measures analysis of variance was then used to  
 206 identify a significant interaction effect between FR condition (30 FR, 60 FR, control) and  
 207 timepoint (baseline, acute, delayed). Where a significant interaction effect was detected, *post*  
 208 *hoc* analysis using least significant difference was performed and a 95% confidence interval  
 209 (CI) calculated. Effect size was also determined for any significant interaction effects using  
 210 Hedge’s  $g$ , which were categorized as <0.2 trivial, 0.2-0.6 small, 0.6-1.2 moderate, 1.2-2.0  
 211 large, 2.0-4.0 very large, and >4.0 extremely large<sup>26</sup>. All data is presented as  $M \pm SD$   
 212 difference,  $f$  value,  $p$  value, 95% CI, and  $g$ .

213

## 214 RESULTS

215 No significant FR condition x timepoint interaction effect was detected for the ADF-ROM  
 216 distance ( $f = 1.63$ ,  $p = 0.19$ ), S&R distance ( $f = 0.80$ ,  $p = 0.54$ ), CMJ height ( $f = 0.83$ ,  $p = 0.99$ ),  
 217 or SJ height ( $f = 0.66$ ,  $p = 0.99$ ; figure 2/table 2). There was also no FR condition effect  
 218 measured across all timepoints for either the ADF-ROM distance ( $f = 2.00$ ,  $p = 0.16$ ), S&R  
 219 distance ( $f = 0.01$ ,  $p = 0.99$ ), CMJ height ( $f = 0.22$ ,  $p = 0.80$ ), or SJ height ( $f = 1.05$ ,  $p = 0.37$ ;  
 220 figure 2/table 2).

221

222  
 223 *Figure 2.* Effects of 60 seconds (60 FR), 30 seconds (30 FR) and no FR (control) on 11 male  
 224 athlete's flexibility and jump performance. Participants performed measures of ankle  
 225 dorsiflexion range of motion (ADF-ROM), sit and reach (S&R), countermovement jump  
 226 (CMJ), and squat jump (SJ), prior to FR (baseline), immediately following FR (acute), and  
 227 following 15 minutes of inactivity (delayed). Error bars =  $M \pm SD$ . \* = significant time effect  
 228 versus baseline. \*\* = significant time effect versus baseline and acute.

229

Table 2. Effects of 60 seconds (60 FR), 30 seconds (30 FR) and no FR (control) on 11 male athlete's flexibility and jump performance.

Test	60 FR (cm)			30 FR (cm)			Control (cm)		
	B	A	D	B	A	D	B	A	D
ADF-ROM distance	12.3 $\pm 1.7$	13.1 $\pm 1.1$	12.2 $\pm 1.2$	12.1 $\pm 0.5$	12.1 $\pm 1.1$	12.2 $\pm 0.8$	11.7 $\pm 1.2$	11.9 $\pm 1.3$	12.3 $\pm 1.3$
S&R distance	17.5 $\pm 7.5$	19.5 $\pm 7.4$	19.4 $\pm 7.1$	17.8 $\pm 7.4$	19.4 $\pm 7.2$	19.0 $\pm 6.9$	18.0 $\pm 8.6$	19.0 $\pm 8.6$	19.0 $\pm 8.8$
CMJ height	32.5 $\pm 5.4$	31.3 $\pm 6.3$	31.0 $\pm 6.5$	32.1 $\pm 4.6$	31.1 $\pm 5.5$	30.6 $\pm 5.3$	32.1 $\pm 4.8$	30.7 $\pm 5.0$	30.4 $\pm 5.3$
SJ height	30.6 $\pm 5.3$	29.5 $\pm 5.6$	28.9 $\pm 5.1$	31.2 $\pm 5.8$	30.3 $\pm 4.9$	29.6 $\pm 5.7$	30.4 $\pm 5.1$	29.3 $\pm 5.0$	28.6 $\pm 5.2$

*Note.* Values are  $M \pm SD$ , ADF-ROM = ankle dorsiflexion range of motion, S&R = sit and reach, CMJ = countermovement jump, SJ = squat jump.

230

231 No significant main effect was detected for the ADF-ROM distance ( $f = 2.32, p = 0.13$ ) across  
 232 all FR conditions, significant time effects were detected for the S&R distance ( $f = 6.58, p =$   
 233  $0.02$ ), CMJ height ( $f = 18.33, p = 0.01$ ), and SJ height ( $f = 27.89, p = 0.01$ , figure 2/table 2).

234 Significant increases in S&R distance of trivial effect size were detected across all 3 FR  
235 conditions from baseline to acute ( $1.5 \pm 0.1$  cm,  $p = 0.03$ , 95% CI [0.2, 2.8] cm,  $g = 0.19$ ) and  
236 from baseline to delayed ( $1.4 \pm 0.2$  cm,  $p = 0.02$ , 95% CI [0.2, 2.5] cm,  $g = 0.18$ ). **These**  
237 **increases did not however exceed inter-trial typical error, which reduces the certainty that they**  
238 **are meaningful.** In addition, no significant difference was detected across all 3 FR conditions  
239 from acute to delayed ( $0.2 \pm 0.1$  cm,  $p = 0.46$ , 95% CI [-0.2, 0.6] cm,  $g = 0.02$ ).

240

241 Significant decreases in CMJ height, of small effect, occurred across all FR conditions from  
242 baseline to acute ( $-1.2 \pm 0.7$  cm,  $p = 0.01$ , 95% CI [-0.5, -2.0] cm,  $g = 0.24$ ) and from baseline  
243 to delayed ( $-1.6 \pm 0.8$  cm,  $p = 0.01$ , 95% CI [-1.0, -2.2] cm,  $g = 0.30$ ). No significant difference  
244 was also detected across all 3 FR conditions between acute and delayed ( $-0.3 \pm 0.1$  cm,  $p =$   
245  $0.24$ , 95% CI [-0.8, 0.5] cm,  $g = 0.06$ ). Likewise, significant decreases in SJ height, of small  
246 effect, were detected from baseline to acute ( $-1.0 \pm 0.2$  cm,  $p = 0.01$ , 95% CI [-0.6, -1.5] cm,  $g =$   
247  $0.20$ ) and from baseline to delayed ( $-1.7 \pm 0.0$  cm,  $p = 0.01$ , 95% CI [-1.1, -2.4] cm,  $g = -$   
248  $0.32$ ). A further significant, trivial, decrease in SJ height was also detected between acute and  
249 delayed ( $-0.7 \pm 0.2$  cm,  $p = 0.01$ , 95% CI [-0.2, -1.2] cm,  $g = 0.13$ ). **Only the mean CMJ**  
250 **decrease from baseline to delayed was above inter-trial typical error, questioning whether the**  
251 **other significant decreases in CMJ and SJ height can be considered meaningful.**

252

## 253 DISCUSSION

254 This study investigated the acute effects of FR durations totaling 30 and 60 seconds on  
255 flexibility and vertical jump performance, and whether any detected acute effects could outlast  
256 a simulated inactive post-warmup preparatory period. The key findings were that, despite  
257 targeting agonist-antagonist muscle pairs, neither 30 FR or 60 FR induced any differential  
258 effects on flexibility or jump performance when compared to no FR.

259

260 It has previously been suggested that discrepancies between previous literature, which have  
261 reported no effect<sup>11,12</sup> or a positive effect<sup>2</sup> of short duration (<60 seconds) FR on flexibility,  
262 might be attributable to differences in FR protocols. Specifically, some of these studies have  
263 targeted muscles in isolation<sup>11,12</sup> rather than agonist-antagonist muscle groups<sup>2</sup>. It has  
264 previously been hypothesized that targeting agonist-antagonist muscle pairs might potentially  
265 increase flexibility via inducing reciprocal inhibition<sup>3</sup>. However, despite targeting lower body  
266 agonist-antagonist muscle groups, the current study reported no effect of 30 FR or 60 FR on  
267 ADF-ROM or S&R, which contrasts with previous findings<sup>2</sup>. Interestingly, compared to the  
268 current study, previous research utilized a textured foam roller (The Rumble Roller) with raised  
269 nodules that is thought to stimulate deeper layers of muscle tissue<sup>2</sup>. Therefore, future research  
270 should establish whether the type of foam roller, and therefore the depth of FR, might influence  
271 the acute effects induced by FR totaling 30-60 seconds. Although conflicting findings exist<sup>2,27</sup>,  
272 a recent systematic review of 14 studies observed that higher density foam rollers appear to  
273 increase flexibility greater than softer density foam rollers due to increased compression of the  
274 fascia<sup>7</sup>. Likewise, the compressive forces induced by FR increase when participants body mass  
275 is higher compared to lower, and the device moves proximally compared to distally.<sup>12,28</sup> Future  
276 research should therefore perform FR with force plates to further quantify these forces and  
277 compare inter-participant differences.

278

279 The finding that neither CMJ or SJ height increased following 30 FR or 60 FR within the  
280 current study, concur with previous studies who report no increase in CMJ height following  
281 FR totaling 30-60 seconds, when compared to controls <sup>2,9,10</sup>. Specifically, other research  
282 reported no difference in CMJ height were reported following FR totaling 60 seconds in  
283 comparison to dynamic stretching or no treatment conditions <sup>2</sup>. Additionally, no improvement  
284 in CMJ height was noted after FR totaling 30 seconds **versus** controls performing planking  
285 exercises <sup>9</sup>, or in comparison to controls mimicking FR movements on skateboards <sup>10</sup>.  
286 Interestingly, research reporting unchanged CMJ height investigated FR in isolation, without  
287 any additional warmup activities <sup>2,9,10</sup>, whereas research reporting increased vertical jump  
288 height combined FR with dynamic stretching <sup>8</sup>. It has been reported that performing FR totaling  
289 60 seconds, without any other additional warmup activities, resulted in no increase in muscle  
290 temperature or muscle contractility (tensiomyography) <sup>12</sup>. Although the current study did not  
291 investigate the mechanisms behind isolated FR, it is known that an increase in muscle  
292 temperature correlates positively with force production <sup>29</sup>. Therefore, it can be speculated that  
293 the duration of FR activity, performed in isolation, within the current study might not have  
294 been long enough to increase muscle temperature and enhance CMJ and SJ height. Thus, future  
295 research could investigate if the mechanisms that underpin isolated FR are influenced by  
296 duration.

297

298 Although the current study did detect significant time effects for S&R distance, CMJ height,  
299 and SJ height, irrespective of FR condition, these findings should be interpreted cautiously.  
300 This is because the means of all, but one detected effect were less than typical error, implying  
301 that most of these detected effects were below the test's measurement error. Specifically, after  
302 applying typical error, only the mean CMJ decrease from baseline to delayed appears above  
303 the measurement error. In contrast, neither the mean CMJ height decrease between baseline  
304 and acute timepoints, nor any of the S&R increases or SJ decreases detected across timepoints  
305 were above typical error. **It should also be noted that, although a repeated measures crossover  
306 design was utilized, a relatively small convenience sample was used. These findings should  
307 therefore be interpreted with caution until further research can be completed.**

308

309 To independently identify the effect of FR activity the current study investigated FR in an  
310 isolated context, however it should be noted that other activities would typically be included  
311 within a well-structured warmup prior to sporting competition <sup>30</sup>. These would likely include  
312 dynamic stretches, as well as higher intensity sport specific exercises that could influence  
313 subsequent competitive performance <sup>30</sup>. Albeit limited, previous research has reported that  
314 when 30 seconds of FR is combined with dynamic stretching vertical jump height is enhanced  
315 <sup>8</sup>. Consequently, further research is required to establish whether, when integrated as part of a  
316 traditional warmup, performing FR for shorter durations might enhance performance and  
317 outlast the post-warmup preparatory period. In addition, it also remains the case that a sporting  
318 warmup must prepare the athlete psychologically for the demands of subsequent competition  
319 <sup>31</sup>. The psychological effects from FR were not investigated in the current study and have also  
320 so far received limited attention within the literature. Although not utilizing FR, research  
321 investigating stretching found that participants believed their flexibility and vertical jump  
322 performance would increase after either static or dynamic stretching, despite no physiological  
323 effect on flexibility or muscle function subsequently being detected <sup>32</sup>. Consequently, this  
324 warrants investigation in future research because any positive psychological findings could  
325 provide an alternative rationale for including short duration FR within a sporting warmup.  
326 **Finally, only jump height was used as a measure of CMJ and SJ performance because of the**

327 applied nature of the research using an Opto Jump. Future research should utilize a force plate  
328 to analyze additional metrics like changes in displacement, time to take off and impulse as  
329 these may indicate difference in jump strategy occurring following FR.

330

### 331 CONCLUSION

332 In conclusion, FR durations totaling 30 or 60 seconds, targeting agonist-antagonist muscle  
333 pairs, demonstrated no increase in measures of flexibility or vertical jump performance beyond  
334 those achieved by an inactive control condition. The inclusion of such short durations of FR  
335 within a warmup therefore remains questionable and requires further investigation before clear  
336 guidelines can be devised.

337

### 338 ACKNOWLEDGMENTS

339 The authors declare no conflict of interests. The authors wish to thank the head coach of  
340 Northumbria University Boxing Club for granting access, as well as all the participants who  
341 volunteered for the study.
