33 **ABSTRACT**

34 The aim of the study was to firstly, present a comprehensive physical profile of international  
35 cricketers in a World Cup winning cricket nation. Secondly, to describe changes in physical  
36 profiles across seven years. Fifty-two senior international cricketers' physical profiles were  
37 retrospectively analysed across seven years. Using linear mixed-modelling, changes in stature,  
38 body mass, sum-of-8 skinfolds, sprinting time (10 and 40 m), run-2 time, counter movement  
39 jump (CMJ), push and pull strength capacity and the Yo-Yo intermittent recovery test level-1  
40 (Yo-Yo-IR1) were analysed during a seven year period. There were no significant changes in  
41 body mass ( $p = 0.63$ ) or stature ( $p = 0.99$ ) during this time. However, there was a significant  
42 ( $p < 0.001$ ) mean decrease of  $\sim 14$  mm in the sum-of-8 skinfolds. Distance covered in the Yo-  
43 Yo-IR1 also showed a significant ( $p = 0.002$ ) effect of years, with a mean increase of 459 m in  
44 2017 when compared to 2014. A significantly ( $p = 0.01$ ) more balanced push-to-pull strength  
45 capacity ratio was also evident across years as a result of a significant ( $p < 0.001$ ) increase in  
46 pull strength capacity. Significant ( $p < 0.05$ ) fluctuations in CMJ, sprint and run-2 time were  
47 seen, with no obvious trends. International cricketers within our study have gone through a  
48 notable physical transformation that has likely resulted in an increase in lean mass and  
49 aerobic capacity. The change across time to a more balanced push-to-pull strength capacity  
50 may be beneficial for injury prevention.

64

## 65 INTRODUCTION

66 International cricketers are exposed to a variety of different physical demands between  
67 positions and across the three match formats <sup>1</sup>. Seam bowlers can produce ground reaction  
68 forces over eight times body mass at front foot contact during their delivery stride <sup>2</sup> and  
69 batters perform in excess of thirty-five 180° turns when scoring a century <sup>3</sup>. In addition, all  
70 cricketers need to be able to perform multiple high intensity and explosive movements whilst  
71 covering large distances across a match <sup>4</sup>. The high variability in time-motion demands of  
72 players from match-to-match also contribute to the complexities of preparing international  
73 cricketers for competition <sup>4</sup>. The increase in international match days may also limit the time  
74 that can be dedicated to enhancing player's physical capacities <sup>5</sup>. As physical attributes have  
75 been associated with critical factors such as ball release speed in seam bowlers <sup>6</sup> and  
76 maximum hitting distance among batters <sup>7</sup>, understanding the physical profile of international  
77 cricketers is essential in assisting practitioners in optimising their preparation.

78

79 Little is known about the physical profiles of international cricketers when compared to the  
80 abundance of research in sports like soccer and rugby. A few studies have presented physical  
81 profiles of professional domestic cricketers <sup>8,9</sup>, with a single study on a top eight international  
82 cricket team <sup>10</sup>. The limitation of the research examining the profiles of professional cricketers  
83 is that it only provides an overview of a discrete point in time. For practitioners to be able to  
84 prepare cricketers effectively for future international competitions it is essential to  
85 understand changes across time. However, data only exist on physical performance changes  
86 across a single year in county and international cricket <sup>8,11</sup>.

87

88 An increase in the match-play time-motion demands of players have been shown in team  
89 sports such as soccer <sup>12</sup> and international rugby <sup>13</sup>. The expectation would be that physical  
90 profiles across sports have improved to meet the enhanced match demands, though there  
91 appears to be inconsistent findings with some studies showing improvements <sup>14</sup>, no change  
92 <sup>15</sup> or even a decrease across years <sup>16</sup> of various physical attributes. With a decrease in available  
93 days for physical preparation in international cricket <sup>5</sup> but an increase in professional physical  
94 preparation support, it is unknown how the international cricketer's profile has evolved.  
95 Literature following the longitudinal physical changes of international sports teams in  
96 preparations for major competition is extremely rare.

97

98 Consequently, the aim of this study is to describe the evolution of the physical profile of an  
99 international cricket nation across a World Cup winning cycle and preparation for the 2019  
100 Ashes series. Given the sensitivity of the international athlete physical profile data, this  
101 analysis will offer a unique insight and assist practitioners in identifying optimal future  
102 profiles.

103

104

## 105 **METHODS**

### 106 *Participants*

107 Fifty-two senior international male cricketers physical profile data from the England men's  
108 team were retrospectively analysed from 2014-2020. All data analysed were collected as a  
109 part of routine testing which all players consent to. To be included in the analysis, cricketers  
110 must have played in at least one Test-Match, One-Day or Twenty20 international sanctioned  
111 match, named in an international squad within the respective year, and be free from injury  
112 as determined by the lead physiotherapist. Table 1 shows the number of matches and players  
113 included in each year. Ethics was granted retrospectively through St Mary's University ethics  
114 committee, in agreement with the Declaration of Helsinki.

115

### 116 *Physical Preparation Overview 2014-2020*

117 Development of aerobic capacity and optimisation of body composition were prioritised  
118 during this period to support players to withstand the congested fixture demands of  
119 international cricket. Due to the low levels of pull strength capacity, there was also a targeted  
120 approach towards a more balanced push to pull strength capacity ratio. However, there was  
121 a lesser focus on speed development.

122

### 123 *Procedures*

124 Stature, body mass, sprint time (10 m and 40 m), countermovement jump height (CMJ),  
125 endurance capacity (Yo-Yo intermittent recovery test level 1), strength capacity (supine row  
126 and press-ups), sum-of-8 skinfolds and run-2 time were assessed across a seven-year period  
127 from 2014 to 2020. Due to changes in preferences of physical tests by the sport science team  
128 and lack of opportunity for a full battery of tests in some years, sporadic years are missing

129 from the data set. Depending on the international fixtures, players were occasionally assessed  
130 at multiple time points throughout the year. If this did occur, the average result across the  
131 year was used, in line with previous research reporting year-to-year changes in physical  
132 profiles<sup>17</sup>. All physical tests were conducted at the same venue (National Cricket Performance  
133 Centre, Loughborough, UK), proceeded by a group warm-up which was led by the team  
134 strength and conditioning coach. The warm-up included sprinting, jumping and 180° turns at  
135 the end of a sprint.

136

137 Body mass was recorded using SECA 862 Scales (Birmingham, UK). The sum-of-8 skinfold  
138 thickness was recorded by two International Society for the Advancement of  
139 Kinanthropometry (ISAK) practitioners using Harpenden callipers (British Indicators,  
140 Hertfordshire, United Kingdom). The standardised sum-of-8 skinfold sites (bicep, tricep,  
141 subscapular, supraspinale, suprailiac, abdomen, mid-thigh and medial calf) and procedures  
142 recommended by ISAK were used. This method has been shown to be highly reliable<sup>18</sup>.

143

#### 144 *Counter Movement Jumps*

145 All CMJ's were performed were strictly vertical on a jump mat using flight time (KMS, Fitness  
146 Technology, AUS). Cricketers were instructed with hands on hips to "jump as high as they can"  
147 and "as they normally would" from a stationary standing position. Three jumps were  
148 performed by each cricketer with 1-min separating each jump. The highest jump was  
149 recorded for analysis.

150

#### 151 *Sprints*

152 Three maximal 40 m sprints with 5 min rest between each sprint were also performed. Dual  
153 beam timing lights (Brower TC, Brower Timing System, Utah, USA) were placed at 0, 10 and  
154 40 m to record 10 m and 40 m splits. All timing lights were mounted on tripods with the first  
155 gate placed at 1 m above the ground and the remaining gates at 1.3 m. Cricketers began from  
156 a split stance position set 0.5 m back from the start line. The fastest time was recorded for  
157 analysis.

158

159

160

161 *Run-2*

162 For the run-2 test, cricketers were timed running between the wickets (two lines 17.68 m  
163 apart). The test is designed to assess the speed of the participants running between the  
164 wickets, as they would in a match. The dual beam timing gates were placed on the start  
165 line/crease and set at a height of 0.6 m. The run-2 was performed with a cricket bat with the  
166 turn assessed off both the right and left side. The test was performed without batting pads  
167 and helmet but with a cricket bat. Cricketers started in the split stance position, 0.5 m behind  
168 the start line with the cricket bat in hand. Cricketers were instructed to slide the bat over the  
169 crease mark at the turn and start/finish, as they would in a match. Two trials, turning off each  
170 the right and left side were recorded with the best trial off each side used to calculate an  
171 average run-2. All sprints and run-2 tests were performed on the same 60 m indoor cricket  
172 training surface as previously described by Ahmun et al. <sup>10</sup>.

173

174 *Push and Pull Strength Capacity Test*

175 The push and pull strength capacity tests are specific tests designed by the England and Wales  
176 Cricket Board (ECB revised testing protocols, unpublished). For the push capacity test,  
177 cricketers lay in a prone position with hands by their side. The first tester placed a fist on the  
178 ground under the cricketer's sternum with the second tester observing from the side and  
179 recording the result. Keeping in time with a metronome set at 1 Hz, the cricketer performed  
180 continuous maximum press-ups. At the top position of the press-up, the cricketer was  
181 instructed to extend their elbows, whilst at the bottom their sternum was required to touch  
182 the tester's hand. The test was ceased if the cricketer did not touch the second tester's hand  
183 with their sternum, did not lock out their elbows, loss of trunk position or failed to keep time  
184 with the metronome. In house test-retest reliability coefficient of variation is 7.6%.

185

186 For the pull capacity test, cricketers lay in a supine, crook lying position underneath a loaded  
187 Olympic bar in a rack. The bar was set at a height where the cricketer was able to reach it  
188 whilst their shoulders are flexed to 90°. The bar was weighted sufficiently so it would not  
189 move. The cricketer grasped the bar and then extended their hip, so the pelvis and lower back  
190 was off the ground. The first tester observed from the side to monitor upper body and arm  
191 position. The second tester observed the lower back and the trunk position. Cricketers  
192 performed maximum supine rows keeping in time with a metronome, again set at 1 Hz. The

193 test was ceased if the sternum did not touch the bar in the top position, the elbows did not  
194 fully extend at the bottom position, loss of trunk position or failed to keep up with  
195 metronome. In house test–retest reliability coefficient of variation is 5.7%. The push-to-pull  
196 strength capacity ratio was calculated by dividing the push strength capacity by the pull  
197 strength capacity.

198

#### 199 *Yo-Yo Intermittent Recovery Test Level-1*

200 Between 2014 and 2018, cricketers performed the Yo-Yo Intermittent Recovery Test Level-1  
201 (Yo-Yo-IR1<sup>19</sup>) to assess endurance capacity. The test consists of running between two lines  
202 (shuttle) set 20 m apart. A further cone was placed 5 m back from the start-finish line for the  
203 cricketers to walk to during the 10 s active recovery between shuttles. The increasing speed  
204 was controlled by an audio beep. The test ended when the cricketer failed to complete two  
205 individual shuttles in the required time.

206

#### 207 *Statistical analyses*

208 Data were analysed using SPSS (version 27.0, Chicago, Illinois, USA). Initially, all dependant  
209 variables were visually screened for normality through histograms and Q-Q plots.  
210 Homogeneity of variance was assessed with Levene’s test. A mixed-linear-modelling (MLM)  
211 was used to assess changes in the dependant variables across years (fixed-factor) with  
212 individual cricketers assigned as random factors in the model. Where a significant fixed-effect  
213 of season was observed, Bonferroni adjusted pairwise comparisons were used to assess  
214 difference between seasons with 95% confidence intervals (CI) present to give a range of  
215 plausible values. Data is reported as estimated marginal means  $\pm$  standard deviation.

216

## 217 **RESULTS**

218 There was no significant fixed effect of year on body mass ( $p = 0.63$ ) or stature ( $p = 0.99$ )  
219 (Figure 1). However, there was a significant fixed effect of years on sum-of-8 skinfold  
220 thickness ( $F_{(5)} = 14.9$ ;  $p < 0.001$ ) (Figure 1C). Pairwise comparisons showed that skinfolds were  
221 significantly lower in 2020, 2019 and 2018 compared to 2015 (2020 Vs 2015;  $p < 0.001$ ; CI 9.9  
222 to 22.9 mm: 2019 Vs 2015;  $p < 0.001$ ; CI 7.9 to 21.5 mm: 2018 Vs 2015  $p < 0.001$ ; CI 7.5 to  
223 21.0 mm) and 2016 (2020 Vs 2016;  $p < 0.001$ ; CI 3.8 to 16.1 mm: 2019 Vs 2016;  $p = 0.003$ ; CI

224 1.8 to 14.6 mm: 2018 Vs 2016  $p = 0.006$ ; CI 1.4 to 14.2 mm). The skinfolds of the cricketers  
225 were also significantly lower in 2017 compared to 2015 ( $p = 0.003$ ; CI 5.8 to 19.5 mm).

226

227 Figure 2 shows changes in Yo-Yo-IR1, CMJ and push and pull strength capacity changes across  
228 years. There was no significant change in push strength capacity across the years ( $p = 0.46$ ).  
229 However, pull strength capacity did show a significant fixed effect across time ( $F_{(4)} = 13.5$ ;  $p <$   
230  $0.001$ ). Significantly more supine rows were performed in 2017 ( $p = 0.03$ ; CI 0 to 13), 2019 ( $p$   
231  $< 0.001$ ; CI 5 to 17) and 2020 ( $p < 0.001$ ; CI 2 to 12) compared to 2014. There were also  
232 significantly more supine rows performed in 2017 ( $p = 0.03$ ; CI 0 to 11), 2019 ( $p < 0.001$ ; CI 5  
233 to 15) and 2020 ( $p < 0.001$ ; CI 2 to 10) compared to 2016. There was also a significant fixed  
234 effect across years for push-to-pull strength capacity ratio ( $F_{(4)} = 4.0$ ;  $p = 0.01$ ). The ratio was  
235 significantly lower in 2019 compared to 2016 ( $p = 0.01$ ; CI 0.1 to 0.8). Yo-Yo-IR1 distance  
236 showed a significant fixed effect across years ( $F_{(3)} = 6.3$ ;  $p = 0.002$ ) with cricketers covering a  
237 greater distance in 2017 compared 2014 ( $p = 0.002$ ; CI 149 to 769 m). There was also a  
238 significant effect of years on CMJ ( $F_{(4)} = 11.6$ ;  $p < 0.001$ ). Compared to 2014 ( $p < 0.001$ ; CI 1.4  
239 to 4.7 cm), 2015 ( $p < 0.001$ ; CI 1.0 to 4.0 cm), 2017 ( $p < 0.001$ ; CI 0.9 to 3.7 cm) and 2018 ( $p =$   
240  $0.03$ ; CI 0.1 to 3.9 cm), 2016 was significantly lower (Figure 2).

241

242 There was a significant fixed effect of years over 10 m sprints ( $F_{(4)} = 4.8$ ;  $p = 0.002$ ) and 40 m  
243 ( $F_{(4)} = 4.5$ ;  $p = 0.003$ ) (Table 2). Cricketers were significantly quicker over 10m in 2016, 2017,  
244 2019 and 2020 compared to 2018 ( $p < 0.05$ ). Forty metre times were significantly quicker in  
245 2017 ( $p = 0.01$ ; CI 0.02 to 0.24 s) and 2016 compared to 2020 ( $p = 0.02$ ; CI 0.01 to 0.23 s).  
246 Finally, there was also a significant fixed effect of years on run-2 time ( $F_{(4)} = 6.6$ ;  $p < 0.001$ ).  
247 Cricketers were significantly quicker in 2019 compared to 2020 ( $p = 0.001$ ; CI 0.04 to 0.24 s)  
248 and 2018 ( $p = 0.01$ ; CI 0.02 to 0.24 s). Run-2 times were also significantly quicker in 2016  
249 compared to 2020 ( $p = 0.01$ ; CI 0.02 to 0.27 s).

250

251

## 252 **DISCUSSION**

253 This is a rare data set that presents physical performance changes of an international cricket  
254 side in their preparations for the 2019 World Cup and Ashes Series. The main findings from  
255 the study were that international cricketers showed a reduction in skinfold thickness across

256 seven years in preparations for the 2019 cricket World Cup and Ashes series. These changes  
257 are independent from any changes in stature or body mass over time, suggesting an increase  
258 in fat-free mass. The endurance capacity of international cricketers was also shown to  
259 improve to comparable levels of other elite endurance team sports. Pull strength capacity  
260 increased, which improved the push-to-pull strength capacity ratio and may be beneficial for  
261 shoulder health. Changes were apparent in sprint times and run-2 time, though no trends  
262 across time were apparent. Given the density of cricket games throughout each year, the data  
263 shows meaningful changes can be made with a targeted physical preparation strategy.

264

265 This is the first study to examine changes in body mass of international cricketers. Previous  
266 research in other sports has shown long-term (~ 60 years<sup>20</sup>) and shorter term (~ 5 years<sup>14</sup>)  
267 increases in body mass in international rugby players, that have been largely associated with  
268 a change to professional status. Conversely, our study showed no changes in body mass over  
269 time within international cricketers. The obvious reasons for the lack of differences in cricket  
270 is it is not a collision-based sport where higher body mass is important<sup>21</sup>. As seam bowlers  
271 have been shown to cover up to 17 km across a single day of fielding<sup>4</sup>, an increase in body  
272 mass over time would be detrimental to performance. Supporting this notion, in running  
273 dominant positions in rugby (backs) have shown no change in body mass across time<sup>22</sup> and  
274 there is also evidence of youth soccer players decreasing in body mass<sup>23</sup> to possibly aid the  
275 increase running match demands of soccer over recent years<sup>12</sup>. It should be noted that upper  
276 body strength has shown an association with maximum hitting distance<sup>7</sup> and consequently  
277 increases in upper body fat free mass may be beneficial for performance in batters.

278

279 Even though there was no change in body mass from 2014 to 2020, there was a substantial  
280 decrease in skinfold thickness. The data from our study suggests that international cricketers  
281 have gone through a drastic alteration in body composition that is likely due to reductions in  
282 bodyfat mass. No data exists on longitudinal changes in body composition within cricket and  
283 there are only limited data presented in other sports. For example, reductions in skinfold  
284 thickness in national level runners<sup>24</sup> and small changes in collegiate sports<sup>25</sup> have been  
285 shown. Decreases in skinfold thickness in our study (18%), are far greater than anything  
286 reported in the literature and would seem to represent a targeted decrease in body fat by  
287 this international team. Given changes in skinfold thickness have been associated with

288 improved running performance, the reduction in skinfold thickness is a vital change in this  
289 international cricket team<sup>24</sup>. The 2020 values reported here are, however, comparable to the  
290 sum of seven skinfold thickness reported in elite Australian fast bowlers in 2007<sup>26</sup>, suggests  
291 total skinfold thickness may have differing temporal characteristics in different countries. One  
292 of the limitations of our study is that due to the small sample sizes in certain years, we were  
293 unable to distinguish between team roles, such as batters and bowlers. Comparisons may  
294 therefore be inappropriate between Stuelcken et al.<sup>26</sup> and our study.

295

296 Only two studies have reported the distance covered during the Yo-Yo-IR1 in professional  
297 cricketers. Veness et al.<sup>9</sup> and Herridge et al.<sup>27</sup> reported mean values of 1892 m and 1960 m  
298 in professional county level cricketers. The highest mean values in our study (2426 m in 2017)  
299 were greater than all mean values reported in a recent systematic review across several  
300 sports, including “top-elite” soccer<sup>28</sup>. This information suggests that international cricketers  
301 have high aerobic capacity, comparable to other elite team sport athletes. Other international  
302 cricket teams have reported lower fitness targets of 1440 m<sup>29</sup>, which would suggest that  
303 there are varying standards in aerobic capacity across different international cricket teams  
304 and domestic cricket. The diverse findings in aerobic capacity reported, make establishing  
305 norm values for cricketers difficult and warrant future research.

306

307 There were improvements in the distance covered in the Yo-Yo-IR1 from 2014 to 2017,  
308 showing an estimated  $\sim 4 \text{ ml}\cdot\text{min}^{-1}\cdot\text{kg}^{-1}$  improvement in  $\dot{V}\text{O}_2 \text{ MAX}$ . The improvement in  
309 endurance capacity appeared to follow similar temporal changes as the decrease in skinfolds  
310 thickness. As previously suggested, the decrease in skinfold thickness has been associated  
311 with an improvement in running performance<sup>24</sup>. Increases in body mass over similar time  
312 periods have also shown to have detrimental effects on endurance capacity in international  
313 rugby players<sup>14</sup>. However, the lack of changes in body mass found in our study would suggest  
314 that the increase in endurance capacity is not solely a result of a reduction in body fat but  
315 reflected an improvement in aerobic metabolism. Anecdotally, these changes reflect a  
316 targeted approach to develop ‘efficient running cricketers’. Despite the reported increase in  
317 game energetics across different sports<sup>13</sup>, there is a lack of data that has reported changes  
318 in aerobic capacity. In addition to the reduction in average aerobic speed in international  
319 rugby players<sup>14</sup>, previous work has shown a  $\sim 2 \text{ ml}\cdot\text{min}^{-1}\cdot\text{kg}^{-1}$  reduction in  $\dot{V}\text{O}_2 \text{ MAX}$  in elite

320 male soccer players over 23 years <sup>15</sup>, while at the same institute no change was reported in  
321 females over 18 years <sup>16</sup>. The increase in aerobic capacity from 2014 to 2017 in our population  
322 are large when compared against the magnitude of change in other team sports and reflect a  
323 positive impact on performance. Due to a higher skill component of cricket compared to more  
324 physiological dominant sports like endurance running, these changes are unlikely to reflect a  
325 physiological selection bias from the coaches.

326

327 There was an improvement in pull strength capacity and a more balanced push-to-pull ratio  
328 across the seven years. The lack of improvement in push strength could possibly be viewed  
329 as negative with previous research highlighting the significant positive correlation between  
330 upper body muscular pushing strength and maximum hitting distance among elite male  
331 cricketers <sup>7</sup>. However, no such relationship between shorter match format (i.e. One-Day and  
332 Twenty20) batting average and strike rate and upper body pushing strength was present,  
333 which would be more influential to individual and team performance <sup>7</sup>. Furthermore, a more  
334 balanced ratio has been proposed to be optimal to minimise injury risk <sup>30</sup>. As around 18% of  
335 all injuries in cricket have been reported to be shoulder related <sup>31</sup> and injuries have been  
336 associated with match outcome in international cricket <sup>32</sup>, a more balanced push pull ratio  
337 found in our study is likely to have a greater impact on performance than improving push  
338 strength.

339

340 Apart from the slower 40 m and run-2 time in 2020 compared to 2016, there were no obvious  
341 sustained trends across years, despite some significant changes. There was also little change  
342 in CMJ over the seven years. Subjectively, we propose that the slower 40 m and run-2 time in  
343 2020 may have been due to the constrained training regime caused by a global pandemic.  
344 The minimal changes pre COVID-19 may also be due to the increasing volume of international  
345 cricket, domestic and franchise cricket <sup>5</sup> and thus decreasing the opportunity to focus on  
346 explosive qualities (e.g. sprinting, jumping and high velocity movements). In other studies,  
347 frequency and duration of aerobic training has shown a negative correlation with strength  
348 and power <sup>33</sup>. The high volume of low intensity running associated with cricket matches may  
349 also have detrimental effects on explosive power adaptations. International cricketers are  
350 exposed to intense, frequent blocks of competition consistently across the whole year, which  
351 is likely to diminish any gains in strength and power from targeted strength and conditioning.

352 However, improvements in power have been shown in aerobic dominated team sports <sup>34</sup>.  
353 Other researchers have attributed minimal change in specific physical qualities towards a lack  
354 of training focus towards them within an institute <sup>16</sup>. The international side within our study  
355 had a focus towards increasing lean body mass and endurance capacity. Consequently, there  
356 are multiple reasons for the lack of change or isolated decreases in explosive qualities within  
357 this group. It should also be noted that whilst some of these changes are significant, largely  
358 these small fluctuations will have minimal impact on cricket performance.

359

360 Whilst the strength of this data is the large sample size in one of the best cricketing nations  
361 in the world, there are several limitations. The data set is from a single international team's  
362 data. Consequently, the changes that have been identified in our study may not apply to other  
363 international teams. Whilst all international sides have a dedicated strength and conditioning  
364 coach, financial and cultural factors and what the head coach wants will all influence the  
365 physical performance changes of the players. Secondly, due to the lower number of cricketers  
366 in some years, we were unable to analyse differences between positions.

367

## 368 **CONCLUSIONS**

369 The international cricketers within our study have gone through a substantial change in body  
370 composition. Without any change in body mass, skinfold thickness has decreased across the  
371 seven years, indicating an increase in lean mass. The 19% increase in Yo-Yo-IR1 distance  
372 covered shows a large increase in aerobic capacity within this group. Cricketers also showed  
373 a more balanced push-to-pull strength capacity ratio which may be beneficial in reducing  
374 shoulder related injuries. No obvious improvement in sprint time, CMJ or run-2 time were  
375 seen across the seven years, which may be as a result of the frequent long duration aerobic  
376 activity which cricketers are exposed to during match play, as well as physical performance  
377 focus on increasing lean body mass and aerobic capacity in this team.
